Discerning some criterion for what it is to be real, for Reality, in the preceding is not as easy as it might seem. One thought is that Reality is the physical. And the physical is that which is studied by the sciences. Still, if science can't explain or explain away consciousness, then reality is not just the physical. Too, reflection might lead us to wonder whether reality comprises a plurality of objects or there is some sense in which it is a unity, whether reality is one. Contemporary science plays a prominent role in determining what's real. So, we might start there.

Reality as Physical: Naturalism

There is nothing more to reality than the natural world, comprising a plurality of objects and properties; this is the view of contemporary naturalism. The natural world is the world revealed to us by the natural sciences. Naturalism stretches back to the ancient Greek atomists, originating in the Epicurean atomistic world view and later Democritus (460 B.C.E.–370 B.C.E), who held that atoms moving through the void and their subsequent collisions (and configurations) are the origin of the world. The first century B.C.E. Roman poet Lucretius' booklength poem *De Rerum Natura* continued the atomistic tradition; the influence of this work continued through the centuries, even influencing the early modern atomists.

Although naturalism is not necessarily committed to physicalism (Goetz and Taliaferro

2007), most naturalists today are physicalists. In what follows, naturalism holds that only the physical is real. (Also, here “materialism” and “physicalism” are interchangeable.) As a view of reality, naturalism has two principal components: (1) an ontological component and (2) a methodological component, where the methods of learning about reality are continuous with the methods of the natural sciences.

The existence and nature of physical objects, their properties, and relations are the subject matter of the natural sciences, understood broadly to include, for example, cognitive psychology, neuroscience, and cognitive neuroscience. To exist, to be part of reality, then, is to be among the objects and properties that are the subjects of scientific inquiry.

It is a matter of some contention, however, what should count as a physical object. One option is to hold that the only real objects are the basic particles identified by physics (quarks, leptons, hadrons, and perhaps quantum fields, according to some). A second is to hold that the only physical objects are those reducible to these basic particles (e.g., Kim 2005). The notion of reducibility is that there are set of rules or “bridge laws” that explain how theories about more complex objects may be ultimately understood as a particular arrangement of more basic particles and their properties. It is controversial whether higher-order objects, such as cells or neurons, and even more complex objects are in fact reducible to the basic particles of contemporary physics.

A third option holds that physicalism includes our ordinary objects along with the objects of our best scientific theories. Although macroscopic objects are not reducible to basic underlying physical objects, they nonetheless *supervene* on those objects. *Supervenience* is itself a difficult concept, and different supervenience relationships have been elaborated. For present purposes, to say that the objects (and properties) of Theory A supervene on the objects (and properties) of Theory B is to say that there can be no changes in Theory A objects unless there is some difference in Theory B objects (McLaughlin and Bennett 2018). That the mental supervenes on the

physical, or more immediately on the neurophysical, is a prominent example of supervenience. For example, Amelia's belief that Jack is a fashion photographer, while not reducible to patterns of neural activity, supervenes on neural activity.

The "poetic naturalism" recently advocated by the physicist Sean Carroll is likely an example of this sort of supervenience relationship. Carroll holds that the basic physical particles are the ultimate foundational structure of reality. Yet there are other theories, especially the "theory" of the world of our ordinary experience, that are replete with people, minds, animals, Gerber daisies, St. Louis, baseballs, iPads, smartphones, and the simple white coffee cup before me that are consistent with basic physical theory (perhaps including quantum field theory) (Carroll 2016). Whether one subscribes to the details of Carroll's view, it has two central features held by many. First, everything that there is – all of reality – is physical. Hence, naturalism. Second, different "levels" of theories capture different aspects of reality. Quantum physics, cognitive neuroscience, and commonsense psychology each describe features of reality.

Although naturalism, because of its insistence that all of reality is physical, rules out the existence of God or angels or nonphysical souls, our interest here is whether a physicalistic naturalism can account for aspects of our mental life, especially consciousness. Some have argued that, for example, physicalism alone cannot explain the *normative* aspects of our experience, such as norms of rationality or ethical norms. Natural science alone cannot explain the nature of the normative. Here, we focus on only one argument about the relation between consciousness, including the sentience of nonhuman animals and self-consciousness, characteristic of human consciousness, and the physical.

The idea of *what it is like* came to prominence with Thomas Nagel's "What Is It Like to Be a Bat?" (Nagel 1974). More recently, his *Mind and Cosmos* argues that naturalism cannot be true (Nagel 2012). Here we focus on the former, which only concludes that we cannot see how to reconcile science with a feature of consciousness.

Types of conscious experience have a *point of view*, which we identify as *subjective*. There is something that it is like to be that type of conscious being. There is something that it is like to be a chimpanzee, a cheetah, and there is something that it is like to be a bat. Nagel says that this point of view is essential to consciousness. Science, however, necessarily abstracts from point of view. By its very nature, science strives for the objective that is to represent the world from *no point of view*. He argues that we do not know how to overcome the apparently irreconcilable essential features of consciousness and scientific theorizing. We cannot do so, he claims, by imagining ourselves inside a bat, as though our human consciousness was a passenger in a "bat mobile." Objective, "no point of view" scientific theory has no way of capturing what it is like, from the internal perspective of a bat, a faithful canine, or a human being. That consciousness is essentially a point of view which means that we cannot fully grasp what it is to be that type of being unless we are that type of being.

In his 2012 work, Nagel insists that consciousness is "the most conspicuous obstacle to a comprehensive naturalism," at least to the extent that naturalism takes scientific theory as the framework for understanding reality. He further claims that if the intractability of the nature of consciousness is correct, then science or naturalism gives us "only part of the truth" (Nagel 2012, p. 11). He further argues that evolutionary science cannot be the complete story of reality.

Physicalists have, of course, responded. It is argued, for example, that we have a very good *objective* understanding of why there are differences in the nature of experience. Such differences arise due to differences in neurophysiology and interactions with the environment. Or, more simply, we can account for subjectivity differences by pointing out that, e.g., Amelia and Alyssa have different brains. Others have argued that the notion of consciousness is not itself clear enough to support Nagel's conclusion (e.g., Daniel Dennett 1991). Or the empirical work on the nature of consciousness by psychologists and neuroscientists will eventually lead us to a satisfactory naturalistic explanation of point of

view (e.g., Bernard Baars 1997; Crick and Koch 1990; Block et al. 1992). Thus, physicalists hold that there is no reason in principle that we could not have explanations of the “what it is like” character of experience.

Those like Nagel who insist on the irreducibility of consciousness understand and accept that, for example, Amelia’s and Alyssa’s physical differences or neurological differences can explain the *fact* of different points of view. Indeed, science may well explain a variety of neural correlations. Still it might be insisted, contra naturalism, that Nagel has indeed provided an “in principle” argument. The “what it is like” character, as far as we can now discern, is a necessarily “first-person” perspective – the subjective – that is not amenable to the third-person or objective viewpoint of scientific theorizing. The inescapably nonphysical character of consciousness is also argued in a widely discussed essay which holds that there is always an aspect of conscious experience not captured by science (Jackson 1982).

The dispute between contemporary naturalism and its critics ranges into many disciplines, not simply whether God exists or consciousness can be explained naturalistically. Since 1969, there has been an ongoing debate about naturalizing epistemology and whether the essentially *normative* features of epistemological theory are properly accounted by naturalism (especially Quine 1969; Kim 1988; see also Crumley 2009, Chap. 7). More recently, naturalists have pushed views that attempt a naturalistic account of values and, thus, of morality. That is, it is held that value judgments and at least certain types of moral theory can be given a biological, evolutionary, and neuroscientific explanation (e.g., Thagard 2010; Patricia Churchland 2012). Again, critics of naturalism have expressed doubts. These intriguing discussions unfortunately cannot be properly addressed here.

The Real Is One: Substance and Idealism

Our experience may tell us that reality comprises a multitude of separate and distinct individuals,

each with uniquely identifying properties. Many philosophers and theologians have, however, thought and argued that reality is but one. Often this single reality is characterized as the *Absolute*. While our experience of many individuals is not delusory, that experience does not reveal the ultimate nature of reality.

Absolutists can be divided into two broad categories, those who approach reality by means of a notion such as substance and those who are idealists. We begin with a substance view of absolutism.

Substance as One

Aristotle (384–322) introduced the notion of *substance* to explain the nature of the real. Benedict Spinoza (1632–1677) argued that a commitment to substance as underlying reality leads to the conclusion that the real is one (Spinoza 1883/1955). Spinoza’s view is best seen against the frame of the history of the notion, stretching from Aristotle, runs through medieval philosophy, and functions centrally in the work of Rene Descartes (1596–1650) (Wolfson 1934/1958). Descartes is well-known for distinguishing within *created* reality two distinct substances: bodies, which have as their essential characteristic *extension* (or, as we might say today, takes up space), and minds, which, while located in time, have as their essential characteristic *thinking*. Descartes also invoked a fundamental sense of substance *that which can exist in and of itself*. In Descartes’s view, only God is substance in this sense, since all other reality depends on divine creativity and preservation for its existence.

Spinoza argues that if substance is that which can exist in and of itself, then there is only one substance. Or: there is only The One. Spinoza refers to this “One” as Nature, God, or Substance. He further held that the logic of the concept of substance was indeed logical and hence the metaphysical structure of reality. In Spinoza’s view, we see a reality discernible (in part) by human reason. Hence the Real is the Rational. In coming to apprehend or being cognizant of that structure, tracing the metaphysically necessary consequences of the concept of substance, we see that reality is one. Gone are distinct

individuals that Aristotle identified as primary substances. For Spinoza, our “individuals” are only particularized manifestations (“modes”) of Substance. Nature or Substance can be viewed as *thought* or as *body*; thought and extension are the two essential attributes of substance. (It is thus sometimes characterized as a dual aspect theory or neutral monism.)

Spinoza identifies substance as that which is *in itself and conceived in itself*. Since Substance is “in itself,” it is independent of any other and thus must be eternal. To have come into existence, Substance would have to either come from nothing or have been created by something else. The first disjunct, however, is logically impossible. *Ex nihilo nihil fit*: nothing comes from nothing. But if the second disjunct were true, then Substance would depend on another for its existence, and hence not “in itself.” There is *only one infinite substance*. Spinoza tells us that if there were two substances, then Substance would be limited by the other and again not in itself.

Informally, our experience presents to us obvious existence. *Something exists*. Asking about the nature of the existent moves us to thinking of independent existence, even if it is the independent existence of many different “existences.” But then reason seems to push us a bit further: what is it to “really” be independent? Here we confront Spinoza’s concept of substance or that which is in itself. Spinoza would hold that the notion he presents of Nature or Substance isn’t merely a chain of logically structured propositions, but he has in fact presented the metaphysical structure of reality: Reality is one, eternal, and infinite. And it is *necessarily* this way. It could not be some other.

If Reality is in fact one, why does our experience present us with seemingly distinct individuals? In Spinoza’s view, experiencing the world as a plurality is a reflection of our necessarily limited perspective. Our ideas are confused because we are but finite modes or manifestations of substance. Reason can partially overcome this limited view, so that we can see that Substance is one. But we will never possess the complete knowledge necessary to grasp fully the essential oneness of reality. We would, in fact, have to

be identical to Substance or God to possess this complete knowledge.

There are some similarities between this view and the *advaita vendanta* of Hinduism, as elaborated and defended by Sankara. Brahman is the fundamental reality, the source or ground of all being. This view perhaps emphasizes the creative aspect of Brahman more than we see in Spinoza. Atman is self-consciousness or the Controller, which is indeed identical with Brahman. Our individual egos (minds) are but the particularized manifestations of Atman. The individual mind is not an independent reality, but neither is it wholly delusory. Our “task” is to come to realize the ultimate structure of reality and to grasp that we are but part of the way in which Atman is manifested (Rambachan 2005).

Absolute Idealism

The Transcendentally Ideal

Idealism of the nineteenth and twentieth centuries is spurred by the work of Immanuel Kant (1724–1804). In his watershed work, *The Critique of Pure Reason*, Kant attempts to overcome the apparent dichotomies of subject and object, of idea and nature, and of rationalism and empiricism (Kant 1929/1965). Kant offered a dramatic critique, or analysis, of the nature and limits of human reason. Doing so, he argues, leads us to see that we can assure ourselves of the existence of empirical reality – the world of our experience – but only by adopting a *transcendental idealism*. That is, we must recognize:

The *a priori* conditions of a possible experience in general are at the same time conditions of the possibility of objects of experience. (Kant 1929/1965, A111)

In Kant’s view, prior philosophy sought to explain our knowledge of the world, and hence to vouchsafe the reality of the content of our experience, by finding those principles or criteria that enabled us to separate out the true from the false in our experience: the mind was to conform to the object. The aim of course was twofold: (a) underwrite our knowledge of the world or reality, and simultaneously (b) reveal the nature of reality as it is in itself.

Kant's new *Copernican Revolution* insisted that "reality" conforms to the special, innate fundamental concepts that organized all of our experience. These concepts he called "categories." His famous transcendental deduction of the categories is an attempt to show that all our experience is organized by precisely these categories. We necessarily experience the world as causally structured – the category of causality at work, comprising a multiplicity of distinct relatively enduring individuals – e.g., the category of substance at work. The objects experienced are indeed spatiotemporal objects, but space and time are the *forms of intuition*. We can only experience the world *through* the forms of intuition and according to the categories. Empirical reality is grounded in the structuring concepts – categories – of our consciousness.

Another *kind* of consciousness might experience the world differently. Given different concepts or categories, the structure of experience, and hence the nature of empirical reality, would be thus different. This feature of Kant's view leads to a much debated issue in the twentieth century philosophy, centered around the notion of a conceptual scheme. This idea of a conceptual scheme – that different sets of categories yield different and perhaps incompatible types of experience – seems to trail in its wake *conceptual relativity*. The issue is still much debated and serves as a line of demarcation between realists, those who hold that there is a single objective reality, at least in part knowable by us, and anti-realists, those who hold that reality is but a reflection of our basic and fundamental concepts.

Kant holds, then, as seen in the above quote, that we know *in advance* – that is, *a priori* – the general nature of any object that we will encounter in experience. These "facts" are reflected in synthetic *a priori* judgments: synthetic because they reveal something about the content of our experience, yet *a priori*. No matter one's particular experience, we know *a priori* that the content of that experience is necessarily structured by the categories.

We are thus guaranteed knowledge of an objective reality, since the conditions of that knowledge are universally accessible. Better: we

are assured that we have contact with an empirical reality, but only on condition of adopting the standpoint of the transcendently ideal.

That transcendental idealism that underwrites empirical knowledge raises one of the more troublesome aspects of Kant's view, the thing-in-itself. Kant holds both that our knowledge of objects is always "framed" by our categories, yet we are justified in claiming that there is indeed a way that the world is *in itself*. Critics have rightly asked how Kant is justified in making such a claim; the thing-in-itself, according to Kant, transcends our categories. But all our knowledge is confined to what can be categorized. Thus, the difficulty appears.

Absolute Idealism

Kant's view leaves subjectivity unreconciled with the real object, the thing-in-itself. Absolute idealism seeks to overcome this gap; it seeks to unify idea and nature. In this the absolute idealism of the nineteenth and twentieth centuries is a return to the absolute idealism of Parmenides' (born c. 515 BC) poem in which he claims that "Being and thought are the same." Idealism, as it is approached here, is the view that the Idea is the active force in the structuring and organizing the course of experience; in particular, the relation of the particulars to the whole or the one that generates them is to be found in the idea. Importantly, nature is part of this one; the idea is not separated from nature. Thus, we have absolute idealism (Dunham et al. 2011, p. 11). Subjective idealism is distinct from absolute idealism and frequently characterized as the view that only minds and their ideas exist, with the attendant corollary that there is no physical world. (Bishop George Berkeley (1685–1753) is thought to exemplify this view.) Absolute idealism in the nineteenth and twentieth centuries included German, British, and American philosophers. Two common themes are the necessary "union" of nature and the idea and hence the "identity in diversity" of subject and object or consciousness and its content.

Seeking the unity of thought and object can be seen as motivating the absolute idealism of Georg W. F. Hegel (1770–1831). Like Parmenides,

Hegel held “the principle that Being is Thought” (Hegel 1949, p. 113). The initial sensuous encounter of consciousness with a particular object is but a first step or stage in the process or unfolding or development of self-consciousness. This sensuous encounter can only be understood, in Hegel’s view, once it is recognized that consciousness is always a self-consciousness. Self-consciousness, in turn, sees thought and the object of thought, which we initially think of as other, as a necessary unity. Self-consciousness always maintains this “double-stance,” seeing the object both as other and as necessarily a part of consciousness. As he remarks, we must see the “ultimate truth not as Substance but as subject as well” (Hegel 1949, p. 80). Unlike that metaphysical tradition that was preoccupied with substance, Hegel thinks we must see our encounter with the world as the activity of consciousness becoming self-consciousness. Consciousness is necessarily an awareness of an object, but it is always aware of itself as consciousness. Thus, thought “comes to itself,” or realizes itself, only in the thinking about an object.

However, these particular “awareness-es” are not enough for thought. Thought necessarily seeks the whole of knowledge, and the whole of knowledge is necessarily an *organized, interconnected system*. At one point, Hegel appeals to the metaphor of the *process* of bud, blossom, and fruit. No one moment of this process explains the whole; it is only in recognizing the stages as moments (Hegel’s term) in the whole that mind or thought or spirit is fully realized (Hegel 1949, p. 68).

He continues that “Science can become an organic system only by the inherent life of the *notion*” (Hegel 1949, p. 111; my italics). *Notion* or *Concept* is a crucial term for Hegel. When we apprehend or become aware of some object, this activity is the notion becoming manifest, or to rely a bit on Plato, it is the process of the universal becoming concrete. As our knowledge continues to grow, as the system becomes more complete, all of these particular moments of the notion manifesting itself in concrete experience progressively draw closer to the Whole or the Absolute or

Spirit, thus being fully realized (also, Dunham et al. 2011, pp. 144–152). In a striking sense, the complete self-realization of Spirit is thus the end of history.

Thought and Being are the same in Hegel to the extent that, as he says, Substance becomes Subject. The Spirit as the Absolute is the organic and total self-realizing of itself.

The tradition of absolute idealism is much richer than these brief paragraphs are able to suggest. But perhaps they suggest something of the scope and depth of this absolute idealist view of reality.

The Necessary, the Possible, and the Impossible

The Necessary

Many have argued that a pluralistic reality comprises not only concrete individuals but also universals, a type of abstract object invoked to explain both our cognitive grasp of categories or types and our apparent references to such types or kinds. In the Platonic dialogues, the *Republic* and the *Symposium*, for example, Socrates contrasts the many instances of or the occurrences of beauty, with the beautiful itself, where we are to understand the latter as the pattern or form or the universal. Every particular beautiful thing or object exemplifies to one degree or another the universal *beauty*. The uniquely identifying feature of universals is that they can be multiply instantiated or exemplified by physical objects or events; the universal wholly occurs in many places at once.

Very briefly, the realist about universals argues that invoking universals is necessary in order to explain our cognitive ability to identify different individuals as being of the same type or category. We “grasp,” according to the realist, that the same universal is instantiated by each of the different individuals. This attribute agreement argument is but one of the arguments deployed by realists about universals.

One interesting feature of universals is that if they exist, they exist necessarily. What is the significance of this “necessarily”? Suppose for a

moment that our world had been different than what it is – perhaps the tectonic plates had different shapes and our mountain ranges were different. Or suppose that Shakespeare never wrote *Hamlet*, or there were eleven not ten amendments in the US Constitution Bill of Rights. To say then that universals exist necessarily (if they exist at all) is to say that no matter what the course of events might have been, no matter how slightly or dramatically different things might have been, universals would still have existed. That is, if realists are right about the existence of universals, then no matter what the world might have been like, universals would have existed in any of those alternate scenarios or “different worlds.”

One simple explanation of this claim is to compare universals to numbers. In any of our alternate courses of events, something would have existed, and thus there would be a *number* of the things that exist. But the same can be said of the *patterns* or *types* exhibited by those objects existing in these different worlds, however many there are. And, as Bertrand Russell once observed about universals, once you’ve acknowledged the existence of one, there seems no sound reason for justifying the existence of any universal.

There is much more that should be said about realism and nominalism. But what about this *different worlds* idea?

Possible Worlds

G. W. Leibniz, as part of his theodicy, claimed that God created the best of all *possible worlds*. In the latter half of the twentieth century, the concept of possible world was given a rigorous treatment by Saul Kripke, enabling more rigorous explanations of modal claims, or the logic of possibility and necessity (e.g., Kripke 1959). Possible worlds are complete alternative ways things might have been. More formal definitions are available, but this will serve here. Amelia, suppose, *actually* is an attorney in Boston. But it makes sense to say that Amelia might have been a surfing instructor in Honolulu. This “might have been” is recast in the language of possible worlds: there is some possible world in which Amelia is a surfing instructor. Possible worlds also serve to

explain the semantics of necessary truths, e.g., to say that “all bachelors are unmarried males” is to say that *in every possible world*, all bachelors are unmarried males.

The explanatory power of the possible worlds framework is widely accepted. But the question quickly arises about the ontological status of possible worlds. Or, in what sense, if at all, are possible worlds real?

One view, espoused and defended by David Lewis, is that possible worlds are real, concrete entities, yet physically inaccessible to us (Lewis 1986). These worlds exist and are populated by various objects, some very much like the objects in this world. In one of those possible worlds, for example, there is someone very much like me who instead became a fashion photographer. That counterpart of me is a real, tangible being; it is in virtue of this “possible world fact” that this modal assertion is true: “Jack might have been a fashion photographer.” Which world is the *real* world? Which is the *actual* world?

A consequence of *possibilism*, as the view is known, is that “actual” is a relative or indexical term. Each possible world, from its “point of view,” is the actual world. “Photographer Jack” is actual – in that possible world. Of course, from our viewpoint, this world is the actual world.

Lewis’ offers as his principal reason for thinking such worlds exist – apart from their explanatory power – is that our discourse about possible worlds commits us to their existence. We can compare this to number theory or physical theory. Theories talk about or refer to, e.g., numbers or electrons. And, the *realist attitude* toward those theories is that the best explanation of their truth and explanatory success is that the objects referred to in such theories *actually* exist. A more technical gloss of this argument: since we quantify over possible worlds, we should accept that they exist.

This view may seem fantastic to some at first glance. Notice, however, the many-worlds interpretation of quantum theory. This view asserts that, in fact, there is more than just our universe; rather a multiverse exists, comprising an ever-increasing number of universes, many very similar to ours, yet they are inaccessible to us.

The most widely held alternative to Lewis' view is *actualism*, a term coined by Robert M. Adams (Loux 1979; Divers 2002). Actualism holds that there is only one actual world – ours – and that possible worlds should instead be treated as abstract objects, like sets or numbers, or, perhaps, universals. One advantage of actualism, critics claim, is that we are better able to make sense of claims such as “Jack might have been a fashion photographer.” How, critics wonder, can reference to some different being, who may differ wildly from me, explain anything about the course of events in my life? Indeed, critics are suspicious that we are even able to refer to such counterpart beings.

As with all of the issues about reality and metaphysics, the literature on the ontological status of possible worlds is extensive, and some of it very technical. There are, however, readable introductions to these topics (e.g., Lowe 2002, Chap. 7).

Of course, it is an easy step from here to a lurking there, namely, does reality include *impossible worlds or beings*?

Impossibilia

Meinongianism is the view that there is some object correlated with every combination of properties, including, strikingly, contradictory properties. Thus, impossible objects – objects having contradictory properties – are beings. Yet impossible objects are nonexistent objects. Only objects in our world exist.

The historical roots of Meinongianism trace to Austrian philosopher and psychologist, Alexius Meinong (1853–1920), who sought to explain the nature of the objects of thought or intentional objects. Since thoughts are necessarily always about “something,” there must be an object for every thought, including thoughts about nonexistent objects such as Santa Claus or unicorns. This view opens the door to thinking about nonexistent objects.

Contemporary Meinongians offer different theories, often tied to appropriate logics for handling “Meinongian objects.” Here a sketch of but one of these views will have to suffice. Graham Priest holds that, in addition to possible

worlds, there are *impossible worlds*. We can talk about nonexistent objects, such as the winged-horse Pegasus of Greek mythology, because Pegasus “exists” in at least one possible world. (There will in fact be many possible worlds in which Pegasus exists.) This winged-horse is, however, a nonexistent object because it is not part of our world, the actual world.

Priest's strategy of impossible worlds also allows for the “being” of impossible objects. Recall that the Meinongian holds that any combination of properties has some correlated object that “encodes” the combination. How are we to understand, say, a round square? Our ordinary understanding is that there are no round squares, because the very notion is self-contradictory. Priest holds that impossible worlds are worlds in which the principle of noncontradiction does not obtain. Round squares thus find their home in impossible worlds because in such worlds, they are not self-contradictory. Now, we cannot consider here the details of the logic (paraconsistent logic) of these impossible worlds. But paraconsistent logic enables us to say something about impossible worlds and the impossible objects that are found in such worlds.

Clearly this is a dramatic extension of our notion of reality. Round squares thus have a type of being or reality. Indeed, Priest has remarked that eventually the Meinongian view will prove closer to the truth than our more “conservative” view (Priest 2016). From the world of ordinary experience to impossible worlds with impossible beings, theories of reality are rich and diverse. Perhaps this brief overview serves to give some sense of that richness.

Summary

This overview hopefully illustrates the richness of the philosophical consideration of the nature of reality. We may begin from common sense – what seems obvious to us in our daily interactions with the world. Yet the most casual reflection opens the door to metaphysics. And once it is claimed that “Reality is nothing but the physical” or “Reality is one” or “The Idea actively

structures the nature of reality,” we are headlong into metaphysics. Perhaps method and metaphysics are inseparable: one’s metaphysical view is tied to the way in which one goes about inquiring into the nature of reality. Different methods may then in part explain the differences in accounts of the nature of ultimate reality. Yet methods help make the questions more precise and the lines of inquiry more fertile. New developments in logic yield new ways of thinking about the necessary and the possible. New conceptualizations of “idea” or “universal” lead to new and richer theories of idealism or realism about universals. Progress in metaphysics is in part due to the richness of the subject and our finding new ways to conceptualize or think about it. “Is there only one object? Or many?” “Is there a limit to the possible?” The scope of such questions hints at their depth. And their depth promises a continued richness and vibrancy still newer and more encompassing theories of reality.

Rhetoric

Sara Greco and Sabrina Mazzali-Lurati

Switzerland

Abstract

Rhetoric is a creative means to design and organize discourse in order for it to be persuasive but not manipulative. Often, the word *rhetoric* is used synonymous with stylistics; but in fact, rhetoric includes the whole process of designing a communicative intervention in response to an *exigence* that emerges in the context. As such, rhetorical discourse is characterized by a specific orientation in relation to its audience, by the importance of the character (*ethos*) of the speaker, and by sound arguments. In particular, at the heart of rhetorical discourse lies the process of *inventio*, that is, exploring possible discursive worlds and identifying appropriate arguments based on sources known as *loci*. Rhetorical discourse has several applications in contemporary communication; prime examples are found in political discourse, business communication, storytelling, and advertising.

Invention

“A hundred years ago, creativity was seen primarily as the province of artists (poets, painters, composers, and of God). Nowadays, everyone is expected to be creative” (Jones 2012, p. 1).

Introduction

A quick search of the British National Corpus, a 100 million word corpus of written and spoken English, reveals that “rhetoric” (occurring 943 times) is oftentimes collocated within negatively

connoted phrases, such as “mere rhetoric,” “just rhetoric,” and “if it is to mean anything more than rhetoric”; or is intended in a negative sense, for example, when “rhetoric” is contrasted with “reality” as in “the tensions between rhetoric and reality are highlighted.” Looking at these collocations, one could infer that rhetoric is a bad use of creativity – a clever use of words to cheat and induce others to do something that does not really correspond to facts. In its origin, however, the word *rhetoric* did not have any such negative meaning. Rhetorical studies originated as a first form of communication studies (Rigotti 1998), and there have been “over two thousand years of reflection in the west” on rhetoric (Fahnestock 2011, p. 6). In his *Rhetoric*, Aristotle states that rhetoric is a *means*; as such, it is not the fault of rhetoric itself if it is put to bad ends – human beings are to blame. Aristotle continues, “true and better [facts] are by nature always more productive of good syllogisms and, in a word, more persuasive” (*Rhetoric* I, 1354b–1355a, transl. by Kennedy 1991, p. 35). Thus, in its original sense, rhetoric constitutes a good use of the possible in discourse, i.e., the art of identifying the various means that can be directed toward reasonable persuasion – based on *ethos* (the orator’s character), *logos* (rational means of persuasion), or *pathos* (the emotive orientation toward the audience and its feelings). Rocci (2017, p. 89), in discussing the work of John of Salisbury, observes that a positive understanding of rhetoric existed in medieval reflection on the liberal arts (Rocci 2017: 92ff).

Reflection on rhetoric originated in ancient Greece around the fifth century BC, in a context in which words held enormous power in the democratic system of Athens. The traditional domains for rhetoric were political, juridical, and epideictic (ceremonial discourse, used to praise or blame someone); each of these domains corresponded to a type of decision that citizens were discussing together in their civic life. The reflection on rhetoric, thus, involved a reflection on audience, persuasive communication, and a basic conceptualization of the communication domains in which public speaking was important (Murphy et al. 2013). Within education, especially in North

America, this aspect has persisted in the tradition of debate handbooks, which teach the fundamentals of argumentative/rhetorical persuasion, with a focus on the domains of public discourse, policy making, and other forms of civic engagement (see Ziegelmueller and Kay 1997; Rieke et al. 2005; and, earlier, the English author Whately 1828/1963).

In the last century, reflection on rhetoric formed part of the renaissance of argumentation studies, traditionally dated to 1958, thanks to Perelman and Olbrechts-Tyteca's (1969/1958) treatise significantly entitled *La nouvelle rhétorique* (*The new rhetoric*), published in the same year as Toulmin's *The uses of argument* (1958). Perelman and Olbrechts-Tyteca (1969/1958) capitalize on ancient rhetoric and apply it to the study of argument-based persuasive discourse in modern societies, with a particular focus on the legal domain. They start from the assumption that reason and rhetoric are connected, and that, in contrast to the evolution of logic since Descartes, reason is not "entirely incompetent in those areas which elude calculation" (Perelman & Olbrechts-Tyteca (1969/1958, p. 3). Rhetoric is the use of reason to form judgments on subjects that are plausible, if noncalculable. As such, rhetoric contains an opportunity: We do not need to "abandon ourselves to irrational forces, instincts, suggestion, or even violence" (ibid.); we can use reason in discourse. The same positive interpretation of rhetoric continues in contemporary studies, which theoretically and empirically examine rhetorical situations and propose rhetorical models of argumentation (cf. Tindale 1999, 2004; Zarefsky 2014).

Rhetoric and Possible Worlds: Where Rhetoric Is Most Creative

A traditional connection between rhetoric and creativity is readily found in the area of rhetorical stylistics (Lat. *elocutio*), i.e., style, or the form or "dress" that a text takes in order to be as persuasive and captivating as possible. In recent centuries, the interpretation of rhetoric as stylistics has been almost inescapable; not least because, as

Fahnestock (2011, p. 7) observes, of all the parts of rhetoric, "style is arguably the most implicated in the others, since linguistic choice is the point of realization for the rhetorical precepts and theories belonging to the other canons." Rhetorical stylistics not only famously concentrates on the persuasive function of figures of speech, but it also covers other levels of text production such as word choice, the construction of sentences, arguments, prosody, and punctuation. Additionally, it includes the rhetorical construction of speaker and audience, and further aspects linked to how discourse is related to the communication context (Fahnestock 2011), including, for example, non-verbal behavior (Lat. *actio*, for some discussion on this term in ancient authors, see Balbo 2018). Rhetoricians study different contexts in which style is important, such as scientific or political discourse and politics (Fahnestock 1999; Zarefsky 2014; Herman 2017). In all these contexts, the emphasis is on how the text achieves the intended communicative goal of persuasion through rhetorical means. Unlike in literary stylistics, in which scholars "attend to texts (fiction, poetry, drama) prized ultimately for their aesthetic value" (Fahnestock 2011, p. 12), rhetorical stylistics looks for functional *regularities* of language and communication (ibid.). It is a different kind of creativity: Creativity in rhetorical stylistics is connected to the capacity for persuasion and the adaptation of discourse to the audience, with an emphasis on the verbal strategies.

Without doing an injustice to this important area, there are other at least equally important aspects through which rhetoric and creativity are connected. We will illustrate these aspects in the following sections, arguing that rhetoric could be seen as a creative exploration of possible worlds, which could be made real if the audience is persuaded by a well-founded speech.

Rhetoric as a Response to an Exigence

Creation always happens in a context. Contrary to what one might assume, possibility arises in reality. Effective messages can be invented only within the perimeter of a concrete situation, with defined goals, rules, and constraints (Testa 2003, p. 107). Far from being opposed to "reality,"

rhetoric stems from the functional interaction between human beings and the environment (Bitzer 1980, p. 21). Invention is triggered by something that is other than it should be in the environment, and it is inspired by the goal to change it. Therefore, rhetorical discourse is a creative exploration of possible worlds and reasoning about alternatives and about “desires, requirements, future possible developments, opportunities and risks, but also (...) counterfactual conditions and consequences, wishes and fictional states of affairs” (Rocci 2009, p. 16). Such exploration is necessary to connect “what *is*” to “what *could be*.” Not by chance, this is what Lloyd Bitzer, in his seminal article on “The rhetorical situation” (1968), identifies as the core of rhetoric. This view, which Bitzer calls *situational*, distinguishes his approach to rhetoric from other approaches, such as the stylistic or scientific approach (1980, pp. 21–22). Rhetorical discourse “functions ultimately to produce action or change in the world” (pp. 3–4), and it originates as “a response to a situation of a certain kind” (p. 3), “which invites utterances” (p. 4), namely a *rhetorical situation*. A rhetorical situation is “a natural context of persons, events, objects, relations, and an exigence which strongly invites utterance” (p. 5). The exigence is pivotal: It is “an imperfection marked by urgency; it is a defect, an obstacle, something waiting to be done, a thing which is other than it should be” (1968, p. 6) and which can be positively modified (“completely or partially removed”, p. 6) by means of discourse that engages the audience “in thought and action” (1968, p. 4): In order to change the current state of affairs, the speaker will try and engage his/her audience to doing something; persuasive discourse is needed to this aim. Together with the rhetor (a term that Bitzer uses interchangeably with “speaker”) and his/her discourse, the rhetorical situation supplies the requirements for a “fitting response” (Bitzer 1968, pp. 10–11, Bitzer 1980, pp. 36–38): It “dictates the purpose, theme, matter, and style of the response” and “prescribe [s] the response which fits” (p. 10). Bitzer’s concept of rhetorical situation gave rise, immediately following the publication of his original essay, to debate and criticism. From the 1970s onward,

different rhetoricians have discussed the fact that the exigence and the other elements of the rhetorical situation are conceived as “located in reality” (1968, p. 11). The controlling/pivotal role of the exigence has been accused of being deterministic and overshadowing the creative power of the rhetor and, in a postmodern view, of the audience. However, this was not Bitzer’s position, as he explained in a later and more detailed articulation (1980, cf. Young 2001). A rhetor’s creativity lies in his/her ability to conceive and produce a discursive response capable of leading the rhetorical audience to act and positively modify the exigence, by adequately taking into account and dealing with the constraints (1980, pp. 23–24). This is not always straightforward, especially when rhetor and audience perceive different rhetorical exigences (1980, pp. 29–31).

Audience in Rhetoric

Thus, rhetorical discourse does not only originate as a response to an exigence, but it is also constructed with an orientation toward its *audience*, which the speaker wants to act in order to modify or “resolve” the exigence. Since the ancient days of rhetoric, audience has been conceived as a central factor of rhetorical discourse. When illustrating epideictic rhetoric, Aristotle observed that “[w]e must also take into account the nature of our particular audience” (Ret. I, 9), including the differences existing between the members of the assembly, particularly the differences in character (Quintilian, Inst. Or. III, 8, 38, see Winterbottom 1970). The ability to adapt to the audience, by taking into consideration the opinions of the hearers and speaking differently to different segments of the audience is an essential trait of eloquence (Cicero 1942).

The crucial importance of the audience for rhetoric is also one of the main elements highlighted in modern and contemporary rhetoric. Consisting of the persons capable of bringing about the positive modification of the exigence controlling the situation (Bitzer 1968, p. 8), the audience is a constitutive element of Bitzer’s rhetorical situation. Perelman and Olbrechts-Tyteca (1969/1958, p. 17) observe that “It is not enough for a man to speak or write; he must also be

listened to or read”, and that often knowledge of an audience must be anticipated in order for the speaker to adapt his or her speech to that audience (Perelman and Olbrechts-Tyteca (1969/1958: 23ff). More often than not, rhetorical discourse addresses “a *composite* audience, embracing people differing in character, loyalties, and functions” (1969/1958, p. 21, our emphasis). Tindale (2015, p. 19) observes that any theory of argumentation should be developed around the concept of audience, and his book *The philosophy of argument and audience reception* is entirely devoted to substantiating this claim. Audience often has a complex structure and requires the speaker to maneuver strategically in accordance with a complex *audience demand* (van Eemeren 2010). Notably, while in interpersonal communication a speaker might know his/her audience well, what often happens in communication to a broader public is that the speaker will make a projection of the different segments of the composite audience.

As illustrated by Jasinski (2001), different scholars have investigated multiaudience rhetorical situations in order to understand how the rhetor can effectively deal with all the different characters and expectations of the different components within the audience (cf. Benoit and D’Agostine 1994; Myers 1999). Among these, the *text stakeholders model* (Palmieri and Mazzali-Lurati 2016) provides a general theoretical framework and categories for the analysis and production of rhetorical texts. This model enables the identification and description of the different components of the audience, typically pertaining to public communication messages; it also allows an analysis of the rhetorical and argumentative strategies deployed by the speaker/writer in order to deal with each component effectively. *Stake* is the core concept in the model: The audience of a text is composed of *text stakeholders*, i.e. individuals or groups that “hold a particular interest, which they expect the text will contribute to fulfilling” (Palmieri and Mazzali-Lurati 2016, p. 481). The notion of the *text stakeholder* arises from the integration of concepts elaborated in different disciplinary fields (Goffman 1981; Rigotti and Rocci 2006; Freeman 1984). Within the text, stakes take the form of *issues*, which the

text is expected to resolve (Palmieri and Mazzali-Lurati 2016, p. 483): Different text stakeholders implicitly or explicitly raise different issues in regard to the text, and the rhetor has to design and produce a message responding to all of the issues raised. Different categories of text stakeholders can be distinguished: The direct *addressee* is “the one who is institutionally expected to be the main mediator of change” (p. 480), while *unaddressed ratified readers* “are not directly addressed by the writer, who however should acknowledge their presence as relevant” because, given their institutional or personal role, “they could raise an important side issue, or, if persuaded on the main issue, they could represent a conduit for persuading the addressee” (p. 480). For *meta-readers*, such as gatekeepers and regulators, the stake “focuses more directly on the text as the by-product of the writing process.” Gatekeepers “decide whether or not to diffuse the text (or part of it) to a larger public”; regulators establish “whether the text can be (legally speaking) published or not, given the legally established requirements disciplining its content, form and style” (p. 480). Finally, there may be *over-readers*, i.e., individuals or groups who “are not entitled to take part in the communicative interaction” and whose “stake in the interaction field is not relevant in respect to the rhetorical exigence” (p. 479).

Topoi-Loci and the Art of “Inventio” as the Most Creative Part of Rhetoric

There is virtually no other area of discourse and communication in which reason and creativity, reflection, and intuition meet so closely and are so tightly interconnected, as the area traditionally named *inventio* in Latin (invention), i.e., the art of seeking out reasons. Renaissance humanist Ralph Lever, in one of the first treatises on rhetoric in English (*Arte of Reason*, Lever 1573), modeled upon Aristotle’s *Rhetoric*, translated *inventio* into the English compound term *witcraft*, which we might in turn translate into “the art of finding astute reasons.” This compound term makes use of “craft,” which is often associated with art and creativity – or, in other words, the exploration of possible worlds; while the term “wit” has a clear connection to the use of reason in an astute way.

Within the discipline of argumentation studies, the process of invention has been explored through the study of *topoi-loci*, i.e., literally, the “places” from which arguments are drawn. In this original metaphor introduced by Aristotle and then conceptually developed in the subsequent Latin, medieval, and postmedieval studies, lists of *topoi-loci* are sketched out with the practical aim of giving support to an arguer who needs to find sound reasons to support his or her claims or standpoints. *Topoi-loci* – for example, “locus from authority,” “locus from efficient cause,” and “locus from analogy” – indicate the sources from which arguments can be constructed.

But what do sterile, abstract structures of arguments such as *loci* have to do with creativity? When you want to support a standpoint, is it not better to just sit down and think – intuitively? This question presupposes that creativity should be linked to instinct, or free thinking; but this is not necessarily true (section “[Rhetoric as a Response to an Exigence](#)”). *Loci* can support creativity because they provide a map of semantic relations, and a map of reasoning connections – and this can assist the arguer to ask the right questions and, thus, find the right arguments. Renaissance humanist Rodolphus Agricola saw *loci* as “*capita rerum*,” i.e., the main semantic nodes (Lat. *capita*, or “heads”) that mirror reality (Lat. *res/rerum*); by studying these nodes and their relations, one will be helped to construct one’s reasoning (Agricola 1539). True, *topoi-loci* are abstract nodes and connections; these abstract connections need to be fleshed out with real premises, shared starting points to become the bone structure of real arguments (Rigotti and Greco 2019). In this way, a seemingly abstract and dry area of rhetorical or argumentative discourse, such as inference, reveals its inner creative nature.

The role of *topoi-loci* in rhetorical creativity has been considered in a series of studies by argumentation scholars who examine contemporary rhetoric, often considering presidential and other political speeches in the USA and elsewhere. It is worth mentioning here the works by David Zarefsky (see Zarefsky 2014). The studies within this tradition demonstrate the *topoi-loci* on which some important speeches have been based and evaluate their validity, including reflecting on

fallacies contained therein; in this sense, the study of rhetoric is not only a description of the strategies used but also an evaluation of their validity. Zarefsky’s analysis (2007) of Colin Powell’s speech to the United Nations on February 5, 2003, concerning Saddam Hussein’s possession of nuclear arms is a case in point. Zarefsky highlights the rhetorical structure of the speech and shows how the speech was persuasive because of Powell’s personal *ethos* (authority) at the time and because of judicious use of the *argument* (locus) *from ignorance*, which allowed Powell to use scant evidence to instill the suspicion that Iraq possessed weapons of mass destruction because no evidence to the contrary was present. Zarefsky reconstructs and criticizes the use of these *topoi-loci* from authority and from ignorance as rhetorical strategies that were persuasive in this case but that were ultimately not well-founded, particularly in the case of the argument from ignorance – something that Powell himself later regretted (Zarefsky 2007). This case is exemplary of studies in argumentative rhetoric, which are concerned not only with style but also with profound logical strategies, and not only with persuasion but also with truth and evidence.

Business Rhetoric: An Example of Creative Rhetoric in Contemporary Communication

Because argumentative discourse is not something that is the preserve of an élite but is widely requested in today’s professional world of communication and beyond, the study of *topoi-loci* and of rhetoric in general has an educational value (Kienpointner 2012). Rhetoric is important in enhancing both what is called “small c creativity,” i.e., everyday creativity, especially in relation to verbal and multimodal productions, and “big C Creativity,” which “refers to the creativity of world-changing works of art or scientific discoveries that alter the way people think about a certain problem or domain” (Jones 2012, p. 2). Business activity is a typical sphere of “small c creativity”: It is dotted with – even constituted of – a series of texts and messages, often dealing with practical questions or problems, belonging to routine and

common genres, which, however, challenge the manager/writer's creativity to find the "fitting response." Therefore, for decades, rhetoric, rhetorical analysis, and rhetorical criticism have been integrated in the practice of and research into organizational and business communication and management. The origins of organizational and business rhetoric, and the variety of developed analyses, themes, approaches, and streams of research, have been thoroughly reviewed and discussed in numerous complementary works (cf. Meisenbach and Mcmillan 2006, Browning and Hartelius 2018, Cheney et al. 2004, Lee 2019).

Typically, communication in organizations, especially commercial companies, involves multiple audiences (Cheney et al. 2004; Huettman 1996; Schriver 1992; Hoffman and Ford 2010). When producing organizational messages, managers need to face these audiences and communicate strategically with them for the sake of the organization's success. Managers need to produce persuasive communicative messages "that reflect the organization's needs and goals" (Browning and Hartelius 2018, p. 88) and that take into account the interests and issues raised by all the different text stakeholders. As Browning and Hartelius (2018) put it, "persuasion is part of an organizational leader's role" (p. 88) and this persuasive element of managers' activity turns them into rhetors. A prime example of this is (digital) storytelling in organizations, which counts as an example of small c creativity. Storytelling persuades (Bendoni 2017, p. 142) or influences (Bendoni 2017, p. 143) the reader/listener. As we may say, it has a clear rhetorical and argumentative function based on the "persuasive power of words and images" (Bendoni 2017, p. 143), even though one might observe that studies on storytelling tend to neglect a more *critical* attitude that the audience or listener might and should adopt in argumentative rhetoric (Rocci 2017, p. 99). Another typical small c creativity rhetorical activity in business can be found in advertising. Studies of rhetoric and argumentation in advertising posit the need to overcome the "verbal/visual divide" (Tseronis 2018) and include more dimensions than just the verbal mode (cf. Groarke and Kišiček 2018). Multimodal tropes and figures in advertising – for instance, metaphor

(Pollaroli and Rocci 2015) and metonymy (Rocci et al. 2018) – are analyzed as "patterns of thought and reasoning" (Kjeldsen 2012). From a rhetorical viewpoint, these patterns are related to different topoi-loci, which are activated in rhetorical discourse (Pollaroli and Rocci 2015); together with the verbal content, they provide the viewer with cues about the inference path proposed by the text and maximize the rhetorical effectiveness of the argument advanced. Rhetorical topoi-loci can equally be effective as means to create advertising campaigns. For example, Marsh (2007) discusses the causal topoi-loci (as derived from Aristotle's reflection on different types of causes) and their role within "a detailed, systematic heuristic for product analysis, an indispensable part of idea generation" in advertising copywriting (Marsh 2007, p. 183).

Ethos, *logos*, and *pathos* (section "Introduction") are considered prominent rhetorical tools in organizations, which are applied to the analysis of organizational messages. For instance, Brennan and Merkl-Davies (2014) analyze the use of the three rhetorical appeals in the press releases relating to the 2011 "Detox" campaign, a public controversy between Greenpeace and international sportswear/fashion firms about the use of hazardous chemicals in the companies' supply chains. Hyland (2005) illustrates how meta-discourse contributes "to creat[ing] the rational, credible and affective appeals" (p. 75) in letters by CEOs in annual reports. Hyland's purpose also has the practical side of "help[ing] students of academic and business communication to develop a more effective rhetorical and verbal repertoire to better operate in the professional domains" (p. 85). Several other studies relating to different areas of organizational and, more particularly, business activity have used *ethos*, *pathos*, and *logos* as analytical tools to provide useful insights for text production. Green (2004), for instance, observes the role of discourse and rhetoric in the diffusion of new managerial practices and proposes a rhetorical theory of diffusion, which describes how "[p]athos, logos, and ethos appeals may combine to shape the speed and extent of diffusion" (p. 660) and identifies the most effective combination and sequence. Tirdatov's (2014) analysis of a sample of successful Kickstarter crowdfunding

campaigns aims to clarify how appeals to ethos, pathos, and logos can be used to create effective crowdfunding pitches, capable of persuading donors. Higgins and Walker (2012) examine how the three persuasive appeals are used by companies in social/environmental reporting to “isolate the role of persuasion in discursive struggle [...] about the ‘appropriate’ role of business in society” (p. 195).

In studies on organizations, ethos occupies a prominent position in relation to the broad issue of image and reputation. As Baumlin and Scisco (2018, p. 201) put it, ethos is revealed in discourse, but it is also constructed and “much organizational rhetoric aims at creating, maintaining, and occasionally repairing corporate image” (ibid.). The connection between rhetoric and corporate reputation has become a fertile area for studies of corporate ethics. The Aristotelian concept of ethos with its three components (virtue, practical wisdom, and goodwill) is taken as a reference point and is used as a tool to describe and conceptualize corporate reputation (cf. for example, Shanahan and Seele 2015). For example, Flyvholm Jorgensen and Isaksson (2008) analyze a number of advertisements from financial institutes in order to highlight how rhetorical strategies and appeals are used to build credibility and reputation. They propose a “reconceptualized and operational model of the construct of credibility (ethos)” (p. 366), and they show that financial advertisements in international magazines largely rely on the appeal to expertise, suggesting that there is a wide range of further rhetorical strategies that remain unused. Kallendorf and Kallendorf (1985) show how the use of figures of speech in internal and external business communication texts particularly contributes to ethos, by projecting “the image of a thoughtful and analytical person whose ideas deserve to be taken seriously” (p. 43). The same authors, in a later study (Kallendorf and Kallendorf 1989), put forward an “Aristotelian theory of programmatic ethics based in and appropriate to the rhetoric of business” (p. 55). Challenging a misrepresentation of Aristotle’s rhetoric as a technique which can be vulnerable to manipulative use, they highlight that, in Aristotle’s view, language is “a carrier of values”; accordingly, it generates

“arguments of probable validity” and “invites rhetorical scrutiny,” based on “the three rhetorical means of persuasion” and “rel[ying] on discussion and debate” (p. 57).

Summary

In sum, rhetorical discourse arises in response to an exigence that emerges from the communication context in which the speaker finds him or herself. The speaker will explore possible worlds to persuade his/her audience and fill the gap between how a given situation is and how it could be; hence, rhetorical communication encompasses a process of exploration of possible worlds and paths to effectively change reality. We have observed that rhetoric concerns the design and realization of communicative interventions that are persuasive but also well-founded. As such, rhetoric includes the three fundamental elements introduced by Aristotle in his *Rhetoric*. First, is the speaker’s character (*ethos*), which bears an influence on how the message is perceived. Second, is the orientation in relation to *audience*, including a careful attention to different segments of complex audiences. Third, is a well-founded *repertoire of arguments*, which is created with the help of *topoi-loci*, the supporting structures of inference. As demonstrated by the examples proposed above, these aspects are crucial in a variety of contemporary communication domains, which range from political speeches to business advertising and many others.

Abstract

Risk is generally understood as a possibility of an event with potentially negative consequences. In order to judge the risk of an event or activity, individuals need to perceive and mentally represent this possibility and the associated negative consequences. It is therefore often more correct to talk about risk as a subjective construct. Subjective risk perception has been broadly studied, with an emphasis on the acceptance of different kinds of dangers at both individual and societal levels. Research focuses on such things as the

cognitive and emotional characteristics of risk perception (i.e., the psychological approach) as well as on the sociocultural aspects of risks (i.e., cultural theory). This chapter discusses the different layers that characterize the definition of risk and examines some of the scientific approaches to the study of risk. It also includes an analysis of the research methodology on risk perception and highlights the connection between risk and *the possible*.

Keywords

Risk perception · Subjective risk · Risk as analysis · Risk as feelings

Definition

[T]here is no such thing as “real” risk, or “objective risk”. (Slovic 1999, pp. 63)

The definition of risk is complex and far from univocal. In fact, different definitions of risk exist both in the scientific world and in the layperson’s understanding of the concept. A careful analysis of risk as a concept uncovers different layers regarding its meaning, created by the different contexts in which it has been studied and the ways in which it has been characterized, conceptualized, and operationalized over the years.

Laypeople usually associate the word “risk” with the possibility that an unpleasant or unwelcome event can happen. From a scientific perspective, risk is defined by taking into consideration all the elements that compose the idea behind the word “risk,” providing a complete explanation of the concept. The Stanford Encyclopedia of Philosophy offers an example of technical definitions widely used across scientific disciplines. Accordingly, the first element can be conceptualized as risk being a *consequence*; it is described as “an unwanted event which may or may not occur.” For example, a fatal car accident is a risk that can occur when driving a car under the influence of alcohol. Another definition frames risk as a *probability*, describing it as “the probability of an unwanted

event which may or may not occur.” An example of this conceptualization of risk would be to state that the probability of being involved in a fatal car accident when drinking and driving is 45%. Those two definitions are part of a bigger categorization of risk, specifically *risk as analysis*, which “brings logic, reason, and scientific deliberation to bear on hazard management,” and *risk as feeling*, which “refers to our fast, instinctive, and intuitive reactions to danger” (Slovic et al. 2004, p. 311). These two macro-categories belong to the idea that we perceive reality in at least two different ways (Epstein 1994; Evans 2008; Kahneman 2003; Stanovich and West 2000). One way is intuitive and fast, more primitive, and belief-based. The other is rational, more recent, and slower. The perception of risk and its interpretation depend on how information is processed.

Another characterization of risk, referring back to the opening quote, differentiates between objective and subjective risk. Objective risk is described as an actual probability of an unwanted or unpleasant event, and this probability is usually quantifiable. For example, the actual statistics regarding refugees drowning while trying to cross the Mediterranean Sea in order to come to Europe provide an objective measure of risk. The survival of these refugees depends on the type of boat, the winds, how rough the sea is, and the probability of finding a safe place to land, among other factors. Although the probabilities and the specific consequences of these aspects are calculable, we, as humans, almost always give a subjective value to them. Indeed, the perception of risk depends on how the risk is framed and how subjectively it is perceived. An example of the subjectivity of “objective risks” is given below. The United Nations High Commissioner for Refugees report that the absolute number of refugees that died trying to reach Europe by crossing the Mediterranean Sea diminished from 2016 to 2017 (UNHCR n.d.). This statement could lead to the conclusion that trying to cross the sea became less risky. However, data also show that the number of drowned refugees per number of people that tried to migrate increased in the same year (see section ► “Crisis of the

Future”). This statement, on the other hand, leads to the conclusion that crossing the sea became riskier. The two statements are both factually true, but they elicit a different perception of the same risk. It is clear, then, that there is no such thing as objective risk (Slovic 1999), and it is more correct to use the word risk in its subjective connotation. Specifically, the subjective risk concerns personal thoughts, beliefs, and values that determine how we perceive risk and how we subjectively judge risky situations.

Subjective judgments of risks occur frequently. Individuals must assess the threats with which they come into contact every day. However, when making these assessments, most people do not have the appropriate knowledge, skills, or time to objectively deal with those risks (see section ► “Uncertainty”). Instead, they adopt subjective assessments based on information cues that allow people to draw conclusions. These cues refer to the characteristic of the risk itself, exemplified by several dichotomies when judging a risky situation (Slovic et al. 1985). For example, the perception of risk varies if people expose themselves *voluntarily* to the risk or if the exposure is instead involuntary, and if the risk is *chronic* or *catastrophic*. Moreover, subjective risk assessments depend on whether the risk is seen as *common*, such that people are used to it and react calmly in front of it, or *dreadful*, causing people to respond in a visceral and impulsive way. Other factors influencing subject risk assessments include whether the risk is seen as *certainly fatal* or *certainly not fatal*, if it is *known* or *not known* to the exposed, if it is *immediate* or *delayed*, *known to science* or *not known to science*, *controllable* or *uncontrollable*, and *new* or *old*. These characteristics make it possible to create profiles of the perceived risk and compare them on different dimensions.

Different Theoretical Approaches to the Study of Risk

The different definitions of risk are accompanied by different schools of thought on risk perception. Two relatively prominent approaches focus

on how individuals perceive risk (i.e., the psychological approach) and how risk is influenced by culture (i.e., cultural theory). In this chapter, we will predominantly focus on the psychological approach. However, we first briefly describe and discuss the central tenets of the cultural theory of risk.

The main goal of cultural theory is to illustrate that the study of the perception of risk must necessarily take into consideration the social and cultural context. In the frame of this theory, risk perception and risk acceptance are strictly related to cultural adherence and social learning. Thus, people’s value system and judgments belong to social groups and do not happen in a social vacuum (see sections ► “Values” and ► “Norms”). In this frame, risk is defined as “a joint product of knowledge of future and consent about the most desired prospect” (Douglas and Wildavsky 1983, p. 5). The framework of cultural theory is based on the group-grid theory. It posits two dimensions (grid and group) to create typical social positions to represent most of the cultural diversity (Mamadouh 1999). The underlying hypothesis is that these two dimensions have a significant impact on people’s worldviews. *Group* is defined as “the outside boundary that people have erected between themselves and the outside world” (Douglas and Wildavsky 1983, p. 138). This signifies the belongingness of an individual to social groups and his or her degree of involvement in them. *Grid*, instead, refers to “all the other social distinctions and delegations of authority that they use to limit how people behave to one another” (Douglas and Wildavsky 1983, p. 138). This indicates how restrictive and regulated a social context is. The two dimensions then generate four types of social environment or worldwide views that represent the four possible filters to a various number of judgments, values, and beliefs: collectivism, egalitarian, individualism, and fatalism. The attitudes of people toward risk are filtered by these views and, similarly, their social trust in the institutions that regulate risks. Individuals tend to trust people or institutions more when they share the same worldwide view.

The psychological approach to the study of risk, on the other hand, focuses more on the

cognitive and emotional aspect of risk perception. One of the main ideas behind the psychological approach is the *psychometric paradigm* (Slovic et al. 1985). It is explained as a “theoretical framework that assumes risk is subjectively defined by individuals who may be influenced by a wide array of psychological, social, institutional and cultural factors” (Slovic 2000, p. xxiii). The goal of this idea was to use behavioral measures to quantify and model psychological factors in order to provide a better understanding of how people perceive and respond to risks (e.g., natural, technological, behavioral hazards) and judge the annual fatalities related to specific dangers and the level of acceptability of risks.

Early results showed that the concept of risk “meant different things for different people” (Slovic 2000, p. xxiii) and that laypeople and experts estimate risks differently. The two groups were similar in assessing statistical frequencies of deaths. However, while experts’ risk perception corresponded relatively well to the actual statistics, laypeople’s perception differed significantly (Slovic et al. 1981).

Moreover, the relationship between the acceptability of a risk and its perceived risk and benefit is influenced by various characteristics such as knowledge of the risk, the dread it causes, and how much control one has. A factor analysis of the dichotomies mentioned above (e.g., familiar vs. unfamiliar, chronic vs. catastrophic, controllable vs. uncontrollable) led to a model of risk perception that utilizes a two-factor space (Slovic 2000). One factor represents how new, uncontrollable, unknown, delayed, and involuntary risks are perceived to be. The other factor indicates how fatal, dreadful, and catastrophic the risk is perceived to be (Fischhoff et al. 1978). In this space, for example, bicycling was judged to be relatively controllable, known, and at the same time having a low probability of being associated with death. Nuclear power, on the other hand, was perceived as a hazard that is involuntary, uncontrollable, and potentially fatal.

More recent research associated with this approach aimed to show which characteristics of people’s traits, beliefs, and ideologies influence risk perceptions. Results show that worldwide

visions, gender, ethnicity, and trust have an impact on the perception of risk. Specifically, people with an egalitarian preference for power have a higher perceived risk of several hazards than people preferring a hierarchical social order (Slovic 1999), and white males perceive risks to be smaller than women and nonwhite people do (Finucane et al. 2000b). Lastly, trust in scientific risk assessments and in the government seems to be essential in explaining the relationship between risk communication, risk management, and risk perception (Slovic 1999; Slovic et al. 1991).

Research on Risk

The concept of risk is multifaceted, which is mirrored by the scientific research conducted on the topic. In this section, we will present and discuss different methodologies and findings related to research on risk. It is important to note that this research evolved and changed over time. The first attempts of systematically measuring attitudes related to risk were done about a century ago in the 1920s (Thurstone 1928) and subsequently went through methodological changes. In the initial approaches, risk perception was mainly studied using qualitative methods such as semi-structured interviews with open questions conducted in person or by phone. However, the limitations of these methodologies have turned the research on risk perception toward quantitative measurements (Sjöberg 2000). These approaches still represent the predominant methods of the psychological approach in the study of risk nowadays.

The elements that characterize the quantitative research on risk perception can be listed as the type of risk (i.e., the hazard), the dimensions of risk, and the sample used.

The hazards considered in the research on risk perception are various and diversified. They can be categorized according to the kind of source, which can be personal (i.e., depending on people’s own decisions and actions), societal (e.g., risky choices made by politicians and the society), and environmental (related to natural and uncontrollable events). Additionally, hazards can

be classified according to their type, which can be behavioral, technological (e.g., industrial and high-tech products), and natural (e.g., biological and physical consequences of climate changes). Finally, hazards can also be distinguished depending on who bears the consequences of the risk (e.g., whether hazards impact individuals or groups). Examples of the combination of these elements are the risks of unprotected sex or sky-diving that both represent a personal and behavioral risk that can have dire consequences on the self. Nuclear power and pollutions are, instead, risks considered societal and technological and with consequences that involve many people (Wilson et al. 2019). Some of the most common risks studied are large-scale new technologies (such as nuclear power), natural disasters (e.g., floods), and diseases (e.g., AIDS; Rohrmann and Renn 2000).

Compared to the types of risks, the dimensions of risk perception examined in research are more difficult to be categorized due to a large number of studies on the topic. Firstly, it is important to note that most of the studies testing risk perceptions used primarily surveys and questionnaires. Consequently, the dimensions of the risk analyzed depend on the type of questions used in the various studies. A recent paper proposes an overview of the most used dimensions in the study of risk perception (Wilson et al. 2019). The first dimension deals with general risk perception, which is usually measured by items such as “How risky is X ?” or “Indicate the level of risk that X presents to Y .” A second dimension pertains to affective reactions by measuring the feelings (e.g., worry) related to risk perception (see section ► “Emotion”). Examples of the items used by this approach are “How concerned are you (if at all) about X ?” or “When you think about X for a moment, to what extent do you feel fearful?”. Next to the general risk perception and the affective reactions, two more dimensions proposed by Wilson and colleagues are relative to probability and consequences. Perceptions of probability are measured using words such as chances, likelihood, and probability of realizing a risk. For measuring consequences, people are typically asked about the severity or seriousness of an event. Two

examples of items are “How likely is it that X (e.g., an earthquake) will occur this year where you live?” for the probability and “If I did experience X (e.g., an earthquake), it is likely that it would negatively impact me” for the consequences. The last dimension comprises evaluations of risks and benefits, which imply a trade-off in which participants weigh the risks and the benefit of something and then judge which one is more important. In order to measure this characteristic of risk, scales like the Domain-Specific Risk-Taking (DOSPERT; Blais and Weber 2006) Scale can be used. In the majority of the cases, research investigates more than one dimension in order to address the multidimensionality of risk perception. Moreover, the complete way of testing risk perception includes using separate items for affect, consequence, and probability (Wilson et al. 2019).

The last element that characterizes the research on risk perception is the type of sample used. A large number of studies were conducted with ad hoc samples, especially university students. However, research on risk used also cross-cultural samples to test hypotheses related to cultural differences in risk perception. Other research used samples of experts compared to samples of lay-people, in order to understand how expertise impacts risk assessments. The specific characteristics of each sample are important to answer different research questions and allow different degrees of generalization of the findings.

Risk and the Possible

It should now be transparent that risk is a complex concept that can be approached from several angles and studied using different methodologies (see section ► “Complexity”). However, it is necessary to clarify the key to its complexity. The definition of risk itself contains a concept that links to the notion of *the possible*. For example, risk is also defined as “the possibility of an unwanted event which may or may not occur.” *The possible*, understood in the context of the word risk, refers to the uncertainty associated with two of its elements, namely, the *probability*

and the *consequences*. A risky event has a specific *probability* of happening; for example, an earthquake can have a 5% probability of occurring in a specific region. Moreover, its *consequences* are themselves possible. For example, an earthquake can cause the destruction of houses in 30% of the cases, the death of people in 10% of the cases, and damage to industries in the affected area in 2% of the cases. Thus, the occurrence of an unwanted event has a specific probability, and the consequences themselves are also probabilistic. It is evident, then, that dealing with the assessment of risk means dealing with *the possible* expressed as probabilities or likelihoods.

A substantial body of research has shown that individuals, when they make choices or estimate the possible occurrence of events, are often sub-optimal in dealing with probabilities. The possibility of an event or its consequences is calculations that require an in-depth knowledge of a specific risk domain, which is not always present. Additionally, calculations of probabilities, like many other reasoning strategies, are constrained by cognitive limitations. It is virtually impossible to process all possibilities and their corresponding consequences. For this reason, when dealing with uncertainty, people usually rely on heuristics (see section ► [“Heuristics”](#)), instinctive assumptions, beliefs, and feelings. While this saves cognitive resources, it can also lead to systematic errors with severe consequences. Many studies have analyzed specifically how these shortcuts affect risk perception and estimations of the probabilities related to risks.

One of the most common mistakes in the estimation of the probability of occurrence of a risky event is due to the *availability bias* (Tversky and Kahneman 1973). This bias refers to a judgment and decision-making strategy that can lead to errors because people tend to judge the frequency of an event depending on how easily that specific event comes to their mind. It can lead to overestimating the frequency of events that were personally experienced more often or that are more covered by the media. For example, individuals tend to judge the probability of dying due to a terrorist attack as higher than dying due to climate change (Sunstein 2007).

However, official reports show that, for example, in 2012, the deaths per year due to climate changes were 400,000 (Climate Vulnerability Monitor), compared to the 12,000 deaths due to terroristic attacks (this estimation is reduced to 2000 dead when the deaths in Syria, Iraq, Nigeria, Afghanistan, and Pakistan are not considered; Global Terrorism Index; see section ► [“Crisis of the Future”](#)). Two other cognitive mistakes are the *optimism bias* (Weinstein and Klein 1996) and the *illusion of control* (Langer 1975). It was shown that people tend to be more of an optimist about themselves and believe to be less at risk than other people for several adverse events such as getting divorced, having cancer, or becoming addicted to drugs (Weinstein 1980). Research also demonstrated that people evaluate risks as lower when they are considered under personal control and overevaluate the risk of events which are not controllable personally. For example, individuals generally judge taking a plane as riskier than driving a car, possibly due to an overestimation of control when driving (Langer 1975).

Furthermore, an essential factor in risk perception and misinterpretation of risk is the strong connection with emotional reactions. The *affect heuristic* illustrates that individuals often evaluate risks and benefits based on feelings (Finucane et al. 2000a). Positive feelings usually lead to a lower perceived risk and higher perceived benefit, while negative feelings have the opposite effect. In people’s minds, risks and benefits are often negatively related (i.e., a high risk is perceived to have low benefit and vice versa). However, in real life, risks and benefits can also be positively correlated (i.e., activities with high risk result in high benefits). For example, nuclear power is a technology that involves high risks such as nuclear incidents and radiation poisoning, but it also has high benefits such as being a potent source of energy. Studies show that people tend to perceive high risks related to nuclear power, but as a consequence, they also tend to judge the technology as not very beneficial.

Evidently, it is difficult for people to correctly estimate both the probability of an event and the possibilities related to its consequences. It is

precisely this element of possibility, characterized in the definition of risk that gives it complexity and demonstrates how difficult it is to speak about objective risk. Finally, it shows the importance of considering and understanding the intrinsic subjective nature of risk assessment, risk management, and risk communication.

Summary

Risk is present in people's everyday life, and a proper understanding of the mechanisms underlying risk perception is important on various levels. The way risks are communicated and perceived can influence individual and societal acceptance of potential hazards and guide people's reaction toward the risk (Dickert et al. 2015). Studying risk must take into consideration the complexity of the concept, and several approaches have been developed over time to capture different parts of its diverse facets. Some, such as cultural theory, emphasize the social and cultural influences, while others, as the psychological approach, address the psychological, cognitive, and emotional aspects of risk. The methodological approach to the study of risk has also evolved considerably. One of the many fascinating insights that have been uncovered concerns the relationship between risk and *the possible*. Research has highlighted the difficulty people have in mentally representing the potentiality of the risky event's occurrence and the associated negative consequences, as evident in various cognitive biases. Laypeople as well as professionals that need to assess or manage risks should take these subjective distortions in the perception of objective risks into consideration. Understanding risk perception and its many facets can lead to better and safer decisions at the individual and societal level.

Abstract

This entry explores how scientific models represent what is possible; how they are justified; and their functions. Two different approaches to these issues are discussed: the first concerns models “embedded” in a well-confirmed theory; the second concerns models not so embedded. When the former models represent possibilities, they provide us with information about what is possible according to the theory in which they are embedded. They are justified to the extent that the theory is actually confirmed. Models of the second kind cannot rely on theoretical support in the same way. Yet, scientists regularly extract modal information from such models, and they hold some epistemic merit. What could

underwrite their justification is explored. Finally, various functions played by scientific models that represent possibilities are considered.

Models · Target systems · Semantic view of theories · How-possibly explanation · Exploration

Introduction

One important way in which scientists investigate the world is through the construction, investigation, and interpretation of scientific models. Take a simple example: Consider a clockmaker who needs to determine how long the pendulum in a clock should be in order to ensure that each swing of the pendulum takes one second. They might reason as follows. First they realize that if each left-to-right (tick) and each right-to-left (tock) swing is to take one second, then the entire period of the pendulum will take two. They also assume that the pendulum is attached to a frictionless pivot; that the pendulum’s cord is massless and inextensionable; that the bob is a point mass; that the amplitude (i.e., the angle of displacement from the vertical) of the pendulum is relatively low; that the only force acting on the pendulum is gravity; and that the system is governed by the laws of Newtonian mechanics. In doing so the clockmaker has constructed a *model*, in this case the so-called “ideal pendulum,” of their clock.

From the assumptions made, it is relatively straightforward to derive that in the model the period T (in seconds) of the pendulum is given by the formula: $T \approx 2\pi\sqrt{l/g}$, where g is the acceleration due to gravity (in units of length per second squared), l is the length of the pendulum (in the same units of length), and the degree to which the left-hand-side approximates the right-hand-side depends on how low the amplitude of the pendulum is (the lower the amplitude, the better the approximation). By setting $T = 2$ s, and knowing that on earth $g = 9.8$ m/s², it is easy to derive that $l = 0.99$ m (such a pendulum is called a “seconds” or “royal” pendulum, and this result explains why typical grandfather clocks are the size and shape that they are). From the model, the clockmaker can draw conclusions about the actual clock. If they are confident that the friction at the pivot is relatively low, that the cord is light compared to the bob, and so on, then they may conclude that an earthbound pendulum whose length is just short of 1 m will take roughly 2 s to complete a full period, i.e., will take roughly 1 s to tick, and 1 s to tock.

So the ideal pendulum can be used to reason about an actual pendulum. But it does more than this. The model can also be used to reason about nonactual, but in some sense possible, systems too. As a simple example, the model can be used to determine how varying the pendulum’s length will affect its period, even if there is no pendulum on earth of the corresponding length. It can also be used to answer questions like: Were the earth’s gravity different (e.g., if were it more or less massive), how long would the pendulum’s period be? And the model provides an answer, even though assuming that g is anything other than its actual value does not correspond to acceleration due to gravity on the actual surface of the earth (the value of g does vary slightly over the earth’s surface but the discussion here assumes that values of g that are significantly different to 9.8 m/s² are being considered). So the model also provides insight into the possible.

The simple example generalizes: While scientists use models to investigate actual systems, they also seem to use them to reason about possible,

but nonactual, systems. Moreover, for some models, this “modal content” is, in some sense, justified. Unlike “just-so” stories, which provide “cheap” information about possibilities, there are reasons to trust what at least some scientific models tell us about what is possible. Further, given that scientists spend a lot of time investigating these models, presumably they play some useful epistemic functions. The questions then are: How do scientific models represent the possible; under what conditions should we expect this modal information to be justified; and what role(s) do such models play? These questions are the focus of this entry.

A Primer on Model-Based Science

Before addressing these questions, it is useful to provide a conceptual framework for model-based science. Since the ideal pendulum is a paradigmatic example of a scientific model, it is used as an illustrative example. To make things more straightforward the scenario is varied slightly so that the clock is already built with a pendulum length of just short of 1 m, and the clockmaker is using the model to predict (or explain) how long its period will be. The behavior of the clock’s pendulum is the model’s *target system*. This is the part, or aspect, of the world that scientists investigate via their models. Target systems include particular actual systems (like the clock), types of systems (like pendula in general), and as the example of pendula with lengths that do not correspond to any actual pendulum shows, possible but nonactual systems (this way of talking does not engender a commitment to modal realism; one could interpret such models as representing concrete but nonactual systems, but see Frigg and Nguyen 2018, for an alternative way of thinking about models that represent possible targets). As philosophers of science use the term, “target system” covers an incredibly broad class of things, from pendula, to atomic nuclei, population growth, economic markets, and so on (Elliott-Graves 2020, provides a useful discussion of what philosophers of science mean by “target systems”).

Recall that the clockmaker made many assumptions that were false of the actual clock (e.g., that there was no friction at the pivot, that there was no air resistance, and so on). They also applied a theory (Newtonian mechanics) which, while enjoying a considerable amount of empirical justification in certain regimes, is known not to be fully accurate. On the other hand, they employed some true assumptions in their reasoning (e.g., that the length of the pendulum was just short of 1 m). Taking these assumptions together delivers a set of sentences, some of which are true of the actual target, but many of which are false. A question that arises is: Why do scientists trade in false assumptions when reasoning about their target systems? One popular answer in the philosophy of science literature is that, strictly speaking, they do not. According to this view, the set of sentences should be thought of as a *model description* that describes a *model system*, rather than as an attempt to describe the target system directly. This is known as an *indirect* view of scientific models (Godfrey-Smith 2006; Weisberg 2007). The idea being that the assumptions that are written down in scientific journal articles and textbooks specify models, surrogate systems that scientists investigate in their own right, and which, via some comparison with target systems, ultimately afford information about the latter.

What are these surrogate systems? In the context of discussions of more mathematized sciences, it is natural to identify these systems with *structures* (see Thomson-Jones 2011 for a review). In the case of the clockmaker, the structure might consist of a triple of real numbers x , y , and z , with each real number corresponding to a value of T , l , and g , and with the triple acting as a solution to the equation specifying the period of a pendulum. Or more generally in this case, since the equation for the period of the model pendulum is derived from the laws of Newtonian

mechanics, which themselves specify mathematical *trajectories* for the model pendulum, the relevant model may be identified with the trajectory rather than the simple triple. Others prefer to analyze models as *fictions*, often drawing on the literature on the ontology of fictions to analyze them (Godfrey-Smith 2009; Frigg 2010; Frigg and Nguyen 2016; Friend 2020; Thomasson 2020). And yet others take them to be abstract objects, about which little more can be said (Giere 2009). For the purposes of this entry, this debate can be set aside by adopting the minimal claim that models are systems that are specified by model descriptions, and which in turn represent target systems. So the sentences that the clockmaker reasons with specify a model, the ideal pendulum, which, depending on how it is parameterized, in turn represents actual and possible pendula, e.g., clocks, swings, and so on, with different length pendula and different trajectories depending on the force of gravity. This representation relation is often understood in terms of comparing the features of the model with the features of the target it represents (Frigg and Nguyen 2020 provide an extensive overview). The crucial point is that model systems have features and behavior that can be investigated independently (e.g., it makes sense to ask questions like “what is the period of the model pendulum?” without any particular target system in mind), but which ultimately afford us information about their (actual and possible) targets. Figure 1 provides a schematic illustration of the indirect view of model-based science.

This provides conceptual structure to the practice of model-based science. Of particular importance here are the facts that: (i) the focus of discussions of models can be ambiguous between the model systems themselves, or the conclusions drawn from the models, about their target systems; and (ii) that one can construct and investigate a model without specifying its target, in

Scientific Modeling, Fig. 1 Indirect view of model-based science

particular, without specifying whether it is an actual system. As a result, for some models at least, whether they represent actual or possible targets can be a matter of debate, and different ways of thinking about those targets can lead to theorists talking past one another.

Models and Theories

Recall that the clockmaker drew on the laws of Newtonian mechanics in their construction of the model. This is a paradigmatic example of a model that is embedded in a well-confirmed scientific theory. According to a popular view, the “semantic view of theories,” a scientific theory is best thought of as a collection of models, delineated by the laws associated with the theory (van Fraassen 1980; Suppe 1989; Suppes 2002; French 2020). Each model in such a collection satisfies some theoretical laws, although they may differ with respect to their initial and boundary conditions. Thus the laws and initial/boundary conditions are model descriptions in the sense outlined above (and note that the term “laws” is not being used in a theoretically loaded sense here; the laws specify the models, and it is the latter that are important on the semantic view). And so each model represents a target that is possible according to that theory.

Thus, the ideal pendulum model is embedded within a broader collection of models, each of which represents a system that is possible according to Newtonian mechanics. One of these models will be an ideal pendulum with values of $T = 2$ s, $l = 0.99$ m, and $g = 9.8$ m/s², and this represents the clockmaker’s actual clock. Another will be the model with values $T = 1.41$ s, $l = 0.99$ m, and $g = 19.6$ m/s², which represents a possible pendulum whose acceleration due to gravity is twice that on earth, and it tells us that its period would be roughly 0.6 s shorter than a pendulum of the same length on earth. So, such a system is possible according to the theory, even though it does not represent any actual system. Moreover, there is no pendulum model in the theory (meeting the idealization assumptions previously laid out)

with a length just short of 1 m, accelerating due to earth’s actual gravity, that has a period of 5 s. So, such a system is *impossible* according to the theory. In general, the theory will include multiple ideal pendulum models (each corresponding to a different specification of the T , g , and l parameters, or alternatively a different possible trajectory for the bob with different possible initial conditions), as well as many other Newtonian models, including, for example, models representing celestial motion, objects in free fall, projectiles, and so on, all of which are possible according to Newtonian mechanics (see McKinsey et al. 1953 for an illustration of this collection of models). Other scientific theories are associated with different scientific laws, and so correspond to different collections of models.

This is a relatively popular way of thinking about models embedded within scientific theories (although for a different take on the relationship between models and theories, see the classic collection Morgan and Morrison 1999, note that other ways of thinking about the model-theory relationship can also be put to work in understanding how models represent possibilities) The next question concerns the *justification* that is offered for the possibility claims generated in this way. It is not difficult to invent examples of theories and models representing possibilities that lack the justification associated with a well-confirmed theory like Newtonian mechanics. For example, consider the “theory” according to which a pendulum’s period is five times its length, i.e., a theory where $T = 5l$. According to this theory, a pendulum with a 5 s period (whose acceleration due to gravity is the same as one on earth) and whose length is 1 m is possible. In fact, any pendulum of that length will have such a period. This generates a possibility that conflicts with the one generated from Newtonian mechanics; what is possible according to one theory is impossible according to another. But it seems like we are more justified in believing the claim generated from Newtonian mechanics, than we are the other claim. What explains this difference in justification?

Fischer (2016; 2017) argues that the justification for our modal beliefs stems directly from the justification we have in the theories that generate

them. His “theory-based epistemology” (TEM) is the following:

where p is any modal claim, you justifiably believe that p if (a) you justifiably believe a theory that says that p and (b) you believe that p on the basis of this theory (Fischer 2016 p. 238; see also Fischer 2017 p. 22).

where the semantic view is drawn upon to explicate what it means for a theory to “say” a modal claim (Fischer 2017 Sect. 2.1; Fischer 2016 Sect. 4.2). So believing the modal claims generated from the models embedded in the Newtonian theory is justified to the extent that the theory is confirmed, and since there is no reason to believe the cooked-up theory, there is no justification for the beliefs that it generates. (It is worth noting here the conditions under which a theory’s confirmation for a theory carries over to justification about the possibilities represented by its models are not entirely straightforward, since many theories are known to be accurate only in certain regimes. We know that Newtonian mechanics is inaccurate on relativistic scales, and thus presumably lack justification for modal beliefs extracted from Newtonian models that represent systems at those scales. Williams [2019] provides a related discussion as applied to so-called “effective” theories.) The crucial move in TEM is therefore to shift the question: “what justifies our beliefs about possibilities?” to the question “what justifies our belief(s) in scientific theories?”

For this strategy to be successful, some story has to be given about what it takes to confirm a scientific theory. But Fischer’s insight is that this question is already well investigated (he cites Psillos 1999; Lipton 2004; Chakravartty 2007 as examples). So the hope is that the correct account of theory confirmation will provide the conditions under which belief in a theory is justified, and this can then be put to work in justifying the modal beliefs that are extracted from that theory.

But crucially, any reasonable account of theory confirmation will require that confirmed scientific theories are known to accurately represent actual systems. Newtonian mechanics is confirmed to the extent that some of its models accurately represent some actual systems (in certain regimes).

So what gets TEM off the ground is the fact that it applies to theories that include models that represent actual and possible systems; and we *know* that the former are accurate. As such, while TEM provides a neat account of how scientific models embedded within a well-confirmed theory provide us with justified information about possible systems, it cannot account for models that do not have this sort of confirmatory basis. These models are the focus of the next section.

Autonomous Models

Consider another model popular with philosophers of science: the so-called “Schelling model of social segregation” (Schelling 1971, 1978; for a philosophical discussion see Aydinonat 2007). In its simplest formulation, the model can be thought of as a chequerboard with tokens of two different types randomly distributed among some, but not all, squares. For each token, it is “happy” if there are at least n tokens of the same type in its neighborhood (the squares that immediately border the token’s location); and it is “unhappy” otherwise. The model’s dynamics are given by a rule that requires evaluating whether the tokens are happy/unhappy; moving an unhappy token to a free square where it will be happy; and repeating the process until there are no unhappy tokens. The remarkable result of the model is that for almost any initial configuration of the board, and for relatively low values of n (i.e. $n > \frac{1}{3}$), the board will evolve to a segregated state, with contiguous collections of tokens of each type, and few mixed neighborhoods.

The model provides a deep insight into the nature of social segregation; even relatively weak individual preferences for not being in a minority can yield widespread segregation on a macroscale. But what is the nature of this insight?

One option is that the model accurately represents the actual causal factors that give rise to segregation in actual target systems (e.g., residential segregation by race that was historically observed in various US cities): it’s individual preferences for not being in a minority that explain such segregation, not more severely racist

preferences against other races, or racist public policy (e.g., Jim Crow laws). A problem for this approach is that there is evidence that segregation *was*, primarily at least, the result of these latter factors (Rothstein 2017). So while social segregation is driven exclusively by weak individual preferences against being in a minority in the model, it is not obvious that actual residential segregation arises this way. If this is correct, then it is difficult to identify the insight of Schelling's model with the idea that it is an accurate (and relatively complete) representation of actual segregation.

A second option is to argue that the model targets a *particular* causal factor that drives segregation in the actual world, without the goal of representing how this causal factor combines with others to yield segregation (Aydinonat 2007; Mäki 2009; Nguyen 2020). And one way of thinking about this is that the model targets a *possible* system, where weak individual preferences are isolated from the other factors that are known to be in operation. The hope then is that by understanding this possible system (where these preferences act in isolation), one can arrive at partial understanding of the actual system. A third option is to take the model to represent such a possible system, and remain agnostic about whether, or even deny that, the casual factor that is isolated is present in actual segregated systems at all (these options are phrased as if the model represents a concrete but nonactual possible system; as noted above Frigg and Nguyen 2018 provide an alternative way of thinking about these models).

On both of these latter options, one denies that the model, properly understood, should be thought of as representing actual target systems (in the second of the three cases the actual target is indirectly investigated). Rather than inaccurately representing the (complete) primary drivers of residential segregation, the model should instead be interpreted as representing a *possible* mechanism for such segregation. And what the model demonstrates, accurately under this interpretation, is that it is possible for weak individual preferences against being in a minority to give rise to widespread macrosegregation (the second of the three options combines this with the idea that this

possibility is actualized, but in a way that acknowledges that it combines with other factors in the actual world). The model thus provides modal information about the possible causes of segregation (why this is valuable is discussed in the next section).

The next question is: What justifies this modal information (or the beliefs formed on the basis of it)? Again, it would not be difficult to invent a model that represents other possibilities, and yet seems to differ in its epistemic status. Consider, for example, a model containing a single dictatorial individual who chooses where each token resides, and who has a preference for segregated patterns. Again, such a model is not an accurate representation of segregation in the actual world (assuming that the Jim Crow laws are to be analyzed systemically rather than as the result of some particular individual), but there is no problem with the idea that it provides us with information about possible causes of social segregation. While implausible, it is certainly *possible*, in some sense at least, for segregation to arise this way. And yet, there seems to be an important difference in the epistemic status of the two models.

This problem is analogous to the one at the end of section "Models and Theories". But in this instance, it is unclear whether an appeal to a well-confirmed theory in which the justified model is embedded can distinguish between models with respect to their epistemic status. While there is a sense in which the Schelling model could be embedded within a broader collection of models (some of which correspond to different values of n for the happiness thresholds, and others correspond to lattices with different topologies, see Ylikoski and Aydinonat 2014, Sect. 3.1, for a useful discussion), such a "theory" would not be empirically confirmed, at least not in the same way as Newtonian mechanics is empirically confirmed, since the theory would not contain models that we know accurately represent actual systems (one could deny this; one way to account for the epistemic value of the Schelling model is to argue that it does in fact accurately represent certain systems, like segregation by friendship groups at a wedding, and that the

confirmation it gains there carries over to its application to residential segregation).

In general then, how should we think about the justification of models like Schelling's, models that are taken to represent possibilities rather than actual systems? There is no widespread agreement among philosophers of science about how to account for this epistemic merit, but there have been some recent attempts to address the question, in terms of the idea that models that represent possibilities in a justified way are, in some sense, *credible*.

Massimi (2018, 2019) explicates credibility in terms of compatibility with what is known, including consistency with the known physical laws of nature. One way of understanding this is in terms of the view discussed in section "Models and Theories"; credibility means possible according to the theory in which it is embedded. But for reasons already discussed, this will not work for autonomous models, and as Grüne-Yanoff (2009 p. 92) points out, there are many models that represent possibilities that are drawn from sciences that do not trade in "laws of nature," at least in the way that the physical sciences do. On a weaker understanding of "consistency with what is known," credibility could be explicated in terms of *epistemic possibility*, i.e., consistency with knowledge about the actual state of the world, irrespective of whether this involves laws of nature (Grüne-Yanoff and Verreault-Julien 2021). But again, this may be too demanding, some scientifically justified models represent possibilities that *we know* to be nonactual (like the Schelling model, assuming that residential segregation was overwhelming driven by public policy rather than individual preferences). An alternative way of explicating credibility is suggested by Sugden (2000 Sect. 11), who draws on an analogy with realistic fictions to offer two criteria for a model to be credible: It should be internally coherent, and it should cohere with what we know about the actual world, where, crucially, like in the case of realistic novels, "we do not demand that the events of the novel [or model] did happen" (p. 25), or, presumably, are even known to have not happened. One way of understanding this second criterion is to restrict it to certain

limited background knowledge: A model can be credible with respect to some background knowledge, if it is coherent with that knowledge. But one may not demand that the background knowledge include everything that is known about the world; in certain modeling contexts scientists might care about compatibility with some of what we know, even if the possibility represented by their model is ruled nonactual by our complete state of knowledge. This could then provide different forms of credibility, indexed to the kind of background knowledge the model is compatible with (Verreault-Julien 2019a). The question then is how to identify the background knowledge that a credible model should be compatible with. More generally, while "credibility" might help distinguish justified from unjustified modal beliefs extracted from scientific models, this brief discussion highlights that more work needs to be done to explicate what is meant by credibility if it is to perform this role (Sjölin Wirling 2021).

Why Represent Possibilities?

Assuming that there is a justificatory story for the way in which models, of either type, provide modal information, one might further ask: Why do we care? For what purposes do scientists investigate possible system via the construction and investigation of scientific models? A full investigation into this question is beyond the scope of this entry, but it is worth briefly considering some functions of these models.

Scientists care about *explaining* phenomena. Recall that the ideal pendulum model represents both the behavior of the clockmaker's actual pendulum, and how the pendulum would behave, were some of its features different (e.g., if it were a different length, or subject to different acceleration due to gravity). The model thus allowed the clockmaker to predict the actual behavior of the pendulum, as well as answer multiple "what-if-things-had-been-different" questions. According to the counterfactual account of explanation, this is hallmark of a scientific explanation (Woodward 2003). On this account, an explanation of some actual target behavior requires

accurately representing that behavior *and* the features that behavior counterfactually depends upon (these counterfactuals are often understood causally, but see Reutlinger and Saatsi 2018 for a discussion of noncausal counterfactual approaches), in the sense of being able to describe how the behavior would change, were the latter features to change. In the first instance then, models that represent possibilities can be used to investigate these counterfactuals, particularly when they are suitably related to a model that accurately represents the actual target (like the ideal pendulum as applied to the clockmaker's actual clock), and thus they can function to contribute to explanations of actual behavior, via helping scientists explore what-if-things-had-been-different questions.

But, as the example of Schelling's model shows, not all models that represent possibilities do so in a way that is easily combined with an accurate representation of the actual target behavior. Thus, it is difficult to account for the role of such models in terms of providing how-actually explanations (although as Bokulich 2014 notes, whether something counts as a how-actually or how-possibly explanation can depend on the context of investigation). But this does not mean that they are not explanatory at all. Various authors have argued that how-possibly explanations are also an important part of scientific practice (for a useful summary see Verreault-Julien 2019a and the references therein, although as he notes, different authors mean different things by "how-possibly explanation"). Whereas a how-actually explanation accurately represents some target phenomena and the features it depends on, a how-possibly explanation may inaccurately represent such a dependency, but nevertheless offer a possible explanation of the form: It is possible that the target behaves that way because of such and such (e.g., the Schelling model shows it is possible that segregation by race is due to weak individual preferences against being in a minority). It has been suggested that how-possibly explanations are valuable for various different reasons: they perform the heuristic function of telling us where to look for empirical evidence (Resnik 1991); they test possibility/impossibility

claims (Grüne-Yanoff 2009; Fumagalli 2016); they add to a "menu" of explanations (Aydinonat 2007; Ylikoski and Aydinonat 2014); and they contribute to our understanding (Verreault-Julien 2017, 2019a,b) (see Grüne-Yanoff and Verreault-Julien 2021 p. 115 for a useful summary and references of these functions).

Other discussions of the function of such models are not couched in terms of explanation, but seem broadly compatible with the aforementioned ideas. Gelfert (2016) and Massimi (2018, 2019) both focus on "exploratory models," which include models that represent possible systems, and identify various functions that they play in addition to identifying how-possible explanations. These include: models that function as the *starting point* for future inquiry (Gelfert, 2016 pp. 84-85); models that feature in *proof of principle* demonstrations (Gelfert 2016 pp. 85-86); models that assess the *suitability of the target systems* (Gelfert 2016 pp. 93-94); and models that represent various conceptual spaces associated with their target systems, either in the sense of representing *causally possible* mechanisms responsible for target behavior (Massimi 2019 pp. 872-875), or by representing what is *objectively possible*, i.e., by representing entities which are neither known to be actual nor known to be nonactual (Massimi 2018 pp. 548-538; 2019 pp. 875-880). Alternatively, one could think about at least some of these models as functioning to help scientists learn about the formal techniques associated with the theories in which they are embedded, and indeed learn about those theories themselves (Luczak 2017). For example, if Newtonian mechanics includes indeterministic models, then by investigating those models we learn that Newtonian mechanics is compatible with indeterminism.

One thing that is worth noting here is that a number of these functions concern how models that represent possible systems, ultimately at least, contribute toward our knowledge and understanding about actual systems (or alternatively, our actual theories). The representation of possibilities is analyzed as a *means to the end* of learning about actual systems/theories. It remains an open question whether representing possible, but

known to be nonactual, systems *for their own sake* contributes to scientific practice.

As this brief discussion demonstrates, models that represent possibilities potentially perform a number of functions in science. However, these discussions have yet to be analyzed systematically and there is currently no overarching account of how these functions are related to one another (although see Grüne-Yanoff and Verreault-Julien 2021 for a recent step in this direction). Perhaps this is to be expected; the class of models that seem to represent possibilities is vast; and they are found in fields from fundamental physics to economics and social science. There is no obvious reason to expect that such models all function in the same way, and thus the function of individual models in individual disciplines may only be analyzed on a piecemeal basis.

Summary

This entry explores how scientific models represent possible systems; how they do so in a justified manner; and their functions. It provides a conceptual framework for thinking about model-based science, and a discussion of two different classes of models that represent possibilities. A model embedded within a well-confirmed theory is justified to the extent that the theory is justified. Models not so embedded are justified in some other way, most plausibly with respect to the background knowledge with which they cohere. Models that represent possibilities can have a number of functions in science, but these functions have yet to be analyzed in a systematic manner.

Acknowledgments Thanks to Philippe Verreault-Julien for helpful comments on a previous draft of this entry.

Self-Direction

Soila Lemmetty and Kaija Collin
Department of Education, University of
Jyväskylä, Jyväskylä, Finland

Abstract

Self-direction refers to an individual's responsibility and active role in relation to their own activities. It has largely been considered from the perspective of the individual, with self-direction being seen as a characteristic of the person, a linear process, or a feature influenced by the factors surrounding the individual. It is understood as a positive activity that promotes creativity and learning. However, the possibilities for self-direction have been less explored. The theme of self-direction and its possibilities comprise a topical and important perspective in the research on self-direction.

Keywords

Self-direction · Self-directed learning · Adult education · Possibilities

Introduction and Definition

Self-direction has attracted the attention of researchers and those working in the field of education and working life in recent decades. Self-direction means “making [one's] own decisions” and managing one's own work (Cambridge Dictionary 2020). It can be described as an activity that is free of external control. Self-direction has also been described as the activity of directing oneself or the capability of directing oneself (Merriam-Webster's Dictionary 2020). In the context of education, the empowerment of students to become self-directed learners has been an important starting point. The concept of self-direction

has developed especially in the field of adult education and is strongly linked to learning in the form of “self-directed learning” (SDL) (Knowles 1975). Self-direction or SDL has been seen as a characteristic of the individual (e.g., Guglielmino 1977; see also Merriam 2001) and as a linear process (Knowles 1975; Tough 1971), but also as a strategy guiding whole communities or organizations (Lee and Edmondson 2017). Self-direction has also been linked to intrinsic motivation, the idea that an individual is motivated when they are allowed to carry out their own intentions, develop things that are important to them, and act on their own interests (Deci and Ryan 2008).

Discussions on self-direction can be found in many fields relating to adult life, such as education and work, but also in relation to society in general. Modern Western society and its associated individualism are closely related to the theme of self-direction in their emphasis on the freedom and autonomy of adults in making decisions about their own lives. In such a society, adults are seen as capable of creating and controlling a good life for themselves. At the heart of this idea is a neo-liberal view that individuals are responsible for their own well-being and life (Skeggs 2004). The activities of adults should therefore not be restricted or directed; rather, they should be given freedom and autonomy for self-directed activities. The emphasis on self-direction seems justified in this light, but it has also received much criticism. Problems of inequality are considered to be the most significant in terms of individualism and self-direction (Skeggs 2004). There is also a need to examine critically the extent to which society actually offers individuals opportunities to influence to their own lives.

When looking at self-direction from the perspective of individual situations or processes, such as in working life, it has been shown to include many positive aspects. Self-direction would appear to promote individual well-being, motivation, and learning (Edmondson et al. 2012). In addition to autonomy and freedom, self-direction has been described as an important factor in the emergence of human creativity and thus the emergence of new innovations. Recently, especially in the context of educational research,

self-direction and creativity have been seen as being strongly related to each other (Gijbels et al. 2012; Lemmetty and Collin 2020). In everyday problem-solving situations in particular, the processes of SDL and creative activity seem to be intertwined (Lemmetty and Collin 2020). Self-direction thus provides an opportunity for creativity, but what factors produce opportunities for self-direction?

Self-direction: Concept Definition and Critical Debate

It is easy to think of adults as self-directed actors because adults take responsibility for their lives. An adult seem to be able to choose the direction of their life, education, job, spouse, financial status, and number of family members. We often see that in a learning situation, the adult learner is able to search for the necessary information in a textbook, choose the right channels for their learning, set learning goals, and evaluate their own realization. In adult education, the concept of self-direction has from the outset referred to the natural need for adults to act self-directedly (Lindeman 1926). Such a view is based on the psychological definition of adulthood, according to which the individual is able to take responsibility for their own life (Knowles et al. 2012). In practice, the concept of self-direction has emerged in the field of educational sciences as it has become clear that even adults continue to learn in different areas of life, and mental growth does not end with the cessation of physical growth.

An important framework concept for adult education and learning is andragogy, which distinguishes adult education from child education, or pedagogy. According to Lindeman (1926), the learning of adults and children has to be separated because (1) adults are motivated to learn through experience, needs, and personal interests; (2) adults' orientation to learning is broadly based on aspects of life; (3) experience is the richest resource for adults in learning; (4) adults have a deep need for self-direction; and (5) individual differences between people increase with age. From the beginning, then, adults were seen as

self-directed by nature, as individuals able to direct their own learning (Knowles 1984). Self-direction was understood as a very individual-driven phenomenon and activity.

In recent years, the concept of heutagogy has been developed alongside andragogy. Heutagogy is based on the concept of self-determination, which refers to the strong self-control of learners (Agonács and Matos 2019). Heutagogy has been described as a more radical version of andragogy, specifically from the perspective of learner autonomy and individual orientation. According to the heutagogical view, autonomy in learning requires the learner to have the ability and extensive competence to act in various problem situations or in new and foreign situations. The learner must understand how to learn and evaluate the learning process continuously in different situations. To date, there has been no discussion of the factors outside the individual in voluntary learning; rather, attention has been paid to the skills and competences of individuals. Heutagogy has shown that SDL is only possible for highly experienced experts; studies of SDL have found that even experienced individuals need guidance and support when encountering a completely new situation (Candy 1991).

The concept of self-direction has received a lot of criticism in adult education. This criticism has largely focused on the fact that, in SDL, the individual has been seen as an actor, regardless of context (Merriam 2001). In addition, it has been asked why self-direction is regarded as a feature of adults when some adults are highly dependent on structures and guidance (Merriam 2001). Moreover, it has been found that some adults are motivated by external factors such as rewards, whereas children may be excited to learn and act self-directedly out of sheer curiosity. Because of such criticism, the theory has been developed so that there is no longer a dichotomy between adults and children, but rather a continuum: an adult who knows little or nothing about a subject to be learned is more dependent on external factors, such as teacher guidance. Thus, self-direction came to be regarded as something to be pursued in the future, in relation to the learning situation rather than the learner (Knowles 1984). Thus, the

examination of self-directedness has increasingly begun to take into account the abilities and competences of adults in relation to the subject being learned, as well as the various situation- and environment-specific factors that frame self-direction.

Self-direction as Processes and Projects: Toward Possibility

In adult education research, self-direction has been defined from the perspectives of processes and practices. Several process models describing SDL have been produced (e.g., Knowles 1975; Merriam and Caffarella 1999; Tough 1971). The first models were very linear and did not take into account the effects of context, whereas the models developed later took into account not only the actor but also the context, the nature of learning, and the aspects and contents of the strategy process. What the models have in common, however, is that they describe in one way or another the progress of the SDL process and the factors influencing it. The starting point for process descriptions is that the aim of a self-directed process is to achieve the set goals through different stages (Zimmerman 2008). These stages may include, for example, planning, monitoring, managing, and reflecting on learning (Pintrich 2004). The best known of the first descriptions of SDL processes is Knowles's (1975) description, according to which the learner takes responsibility for identifying their learning needs, defining the learning objectives, acquiring the human and material learning resources, and evaluating the learning outcomes. Self-direction therefore extends to all stages of the learning process, from setting the learning objectives to implementing learning and ultimately assessing what has been learned (Brockett and Hiemstra 1991).

Such SDL processes have been regarded as closely linked to creativity and its empowerment. Process theories describing SDL and creative thinking or acting appear to be very similar in terms of their stages and the role of the actor. In a manner akin to the process of SDL, the process

of creativity is often described as an individual's process that progresses through the formation of an idea or the perception of a problem to find the necessary information, create a new idea, and ultimately evaluate it (Amabile 1996). Lemmetty and Collin (2020) found that the steps of SDL may be included in the steps of the creative process, forming a process intertwined with creativity and SDL. When we consider those studies in which self-direction has been described as a factor promoting creativity and problem solving (e.g., Gijbels et al. 2012), we can regard self-direction as offering significant possibilities for creativity, but the question remains: What enables self-direction?

In terms of the process, a broader starting point for examining self-direction in learning has been the project perspective. From this perspective, learning is regarded as taking place within the environment, the community, and the individual (Clardy 2000; Lemmetty 2020). Thus, from the project perspective, the activities of the individual are taken into account but so also are the opportunities for self-direction produced by the environment. Studies (e.g., Artis and Harris 2007; Clardy 2000; Lemmetty 2020) have distinguished between different learning projects depending on the extent of their self-direction. These studies have been carried out in the context of working life. They found that there are a wide range of SDL projects in working life, with learning being strongly driven by external (organizational) factors in some, while in others the individual's opportunities for decision making are wider (e.g., Artis and Harris 2007; Lemmetty 2020). Thus, self-direction occurs in a wide variety of situations, but its scope and level vary.

In addition, studies have identified the factors that influence the possibility of SDL. Lemmetty's (2020) study found that the goals of different learning situations strongly influence how self-directedness emerges. If we imagine a working-life situation in which an employer wants to initiate extensive austerity measures, it is quite typical for them to inform subordinates about the ways in which the savings are to be achieved. In this case, the employees are not left with the opportunity to consider or reflect on

appropriate means themselves; the information and proposed changes come from the organization. At the other extreme is the working-life situation in which the employee perceives a problem during their job and starts to find out on their own initiative its causes, consequences, and possible solutions, setting goals for learning something new and evaluating the end result. In this case, the individual's self-direction can be seen as broad. The two different working-life situations described above may also be seen as SDL projects that differ greatly according to the opportunities the individual has to make decisions and manage the situation. Thus, it is not always the individual's choice as to whether they are self-directed or willing and able to act; the possibility of self-direction depends on the situation.

However, the goal alone is not the only factor that frames self-direction in a learning situation (Lemmetty 2020). Studies (e.g., Baskett 1993; Bell 2017) have also found that while a situation is ongoing, many factors outside the individual affect the way in which the processes of SDL and the creativity it may involve proceed. In the working-life context, the atmosphere of the workplace, the nature of the supervisor's work, collegiality, and cooperation, as well as the work environment and tools available, have been found to be important (see, e.g., Foucher 1995; Lemmetty 2020), thus also affecting creativity.

Self-direction and External Opportunities

Enabling self-direction is influenced by individual factors, desire and motive requirements, and individual skills and competences (Guglielmino 1977; Merriam 2001; Raemondoc et al. 2017), but also by external factors, such as the environment, autonomy, and control (Bell 2017; Lemmetty 2020; Lemmetty and Collin 2019). Self-direction is both a value-generating factor that promotes creativity and learning, and a requirement and obligation for adults in society and working life. For this reason, it is important to look at the relationship between self-direction and

possibility; that is, the kinds of possibility that self-direction requires to manifest.

One significant and interesting concept in the phenomenon of self-direction has been autonomy. Researchers have disagreed somewhat about the role of autonomy in self-direction. According to Deci and Ryan (2008), external events, such as deadlines, imposed goals, pressure on performance, competition, and evaluations, restrict learners' intrinsic motivation and thus also self-direction, because they displace autonomy. Candy (1991) has argued that as long as a learner's autonomy varies from situation to situation, one should not think that if an individual is self-directed in one situation, they will be in another area. Thus, self-direction does not move as a characteristic with a person from one situation to another; rather, the framework provided for the action affects whether self-direction is possible. The autonomy and freedom described above have been seen in several contexts as a precondition for self-direction, but such a view is very narrow since self-direction is not unequivocally achieved through autonomy alone, and some studies have questioned the importance of autonomy for self-direction, finding that self-direction needs strong support (e.g., Bell 2017; Lemmetty 2020) and that no one can operate fully autonomously all the time in, for example, a work environment. Self-direction is thus a much more complex entity, research into which requires more appreciation of the environment and interactions. As Bouchard (2012) has stated, "In the end, any tangible occurrence of self-directed learning undoubtedly involves the interaction of all three aspects, in that it will entail (1) the application of some actions or procedures, (2) by a person who is not psychologically averse to the experience, (3) in an environment, which at the very least does not preclude the emergence of self-directed learning."

Studies have identified, for example, a climate of trust and appreciation as a factor in enabling self-direction (Baskett 1993), as well as a culture that supports experimentation and allows for errors (Foucher 1995). In any new situation, the process of self-direction also requires support and guidance (Bell 2017). Thus, mentoring is part of the SDL process. Whereas in pedagogy, teaching

has been seen as teacher-centered, in andragogy the teacher has been seen as a facilitator, whose job is to coach the learner to reach better outcomes. Supervisors, managers, and colleagues can be seen as playing a similar role in the context of working life, which is why their role in supporting self-direction is not to tell anyone how to do something but to involve the employee in the work process by discussing the needs of the situation together (Foucher 1995; Knowles et al. 2012).

Self-direction needs commonly stated and understood goals in the community (Kops 1997). However, in the workplace, for example, the different interests and goals of the actors can often create confusing situations. If everyone works in a self-directed way toward their own goals, there will be no certainty that a common goal will be achieved. For this reason, as an individual phenomenon, self-directedness works poorly in communities or societies, where everyone should act according to the particular rules of the game, guidelines, or laws so that bigger goals can be achieved. For this reason, self-direction should be seen as limited: It does not necessarily extend to individual-oriented goal setting or even evaluation of activities, but to individual decision-making moments that emerge during the process (see Lemmetty and Collin 2019). Thus, self-direction should be seen as a framed and situational phenomenon that alternates and interacts with external factors.

Concluding Thoughts

If we recognize that self-directedness stems from everyday problem-solving situations that individuals focus on, for example, in their work, one must consider whence the problem derives: Is it, for example, a customer's need or perhaps a business-related challenge? If the problem arises from something other than the individual's personal need, it is worth noting that its solution – through self-directed action – is always realized in relation to the situation. In such cases, the meaning of autonomy will be blurred, and the importance of other situational frames will increase.

In many fields of life, human activity is guided by some “external” factor, in which case self-directedness is not always an activity aimed at achieving one’s own goals. However, one of the assessments is that in an individualistic society and in working life, where individuals are expected to take on an ever-greater responsibility for their own work, learning, and life, it is often the responsibility of the actors themselves to decide how different goals can be achieved. Thus, self-direction occurs, if not in the setting of goals, then at least in moving toward them. Along the way, however, there are several factors, ranging from interaction, tools, fellow human beings, and affordances, that interact with and affect individual self-direction. Moreover, the relationship between autonomy and support in enabling self-direction in each situation remains partly unconscious (Bell 2017; Lemmetty 2020)

In the future, self-direction should be seen as a broader socio-cultural entity, arising in different situations and contexts. Self-directed research has focused on educational and working-life situations, but the applicability of prevailing theories and perspectives to different age groups (e.g., children, adults, and the elderly) and contexts (such as hobbies and organizational work) is unclear. For this reason, we still need a better understanding of the relationship between self-direction and possibilities.

Self-Regulation

Aleksandra Zielińska and Maciej Karwowski
Institute of Psychology, University of Wrocław,
Wrocław, Poland

Abstract

This entry discusses the role of self-regulation in fulfilling personal goals. Particularly, it focuses on creative actions representing one

of the most salient forms of engaging with *the possible*. Different conceptual views on self-regulation are discussed, with a particular focus on the holistic approaches to self-regulation, considered best suited for explaining how people guide their creative endeavors. Specific self-regulatory mechanisms considered beneficial when pursuing a creative goal are presented. The significance of conducting intervention programs focused on strengthening self-regulation is emphasized.

Keywords

Self-regulation · Creativity · Creative activity · Creative goal · Uncertainty · Creative self

Opportunities drive people's actions. We formulate our goals, strivings, and pursuits based on the acknowledgment or anticipation that something is indeed possible to achieve. Such an encounter with the possible spurs to exploration, to discover various avenues to follow. Simultaneously, it motivates goal-directedness: an orientation towards a desired state or outcome. This peculiar tension between staying open to the emerging opportunities and canalizing the efforts to the most promising option sometimes referred to as exploration-exploitation tradeoff (Mehlhorn et al. 2015), characterizes a creative action – one of the most prototypical processes of actualizing the possible. Dealing with complexity requires various control and modulatory processes to be engaged as they allow the person to observe, change, and adjust the way of striving for a goal. A broad spectrum of processes vital for a successful goal pursuit has been collectively termed *self-regulation*.

In this entry, we discuss how people engage with the *possible* from the perspective of self-regulation. We highlight the importance of various self-regulatory mechanisms for effective goal realization, especially in pursuing a *creative goal*. We begin by discussing select theoretical views on self-regulation and pointing to its conceptualizations' plurality. Then, we discuss how self-regulation may support creative actions, considered one of the most salient forms of

actualizing the possible. Consequently and finally, we propose why self-regulation should take a more prominent place in debates on encouraging people to seize their creative potential and make them more efficient in realizing the possible.

Varieties of Self-Regulation

In a broad sense, self-regulation refers to the ability and skill to manage own activity adaptively to a context and in a given timeframe. Being often defined in terms of goal-directed behavior (Hofmann et al. 2012; Karoly 1993) or a purposeful action (Bandura 1991), it represents a crucial component of personal strivings, implementing ideas, turning potential into real-life actions and accomplishments, or – in other words – *materializing the possible*. Indeed, effective self-regulation has been found pivotal for a wide range of positive outcomes, such as academic performance (Duckworth and Seligman 2005), health (Hagger et al. 2009), job satisfaction and performance (Wang et al. 2021), or financial well-being (Strömbäck et al. 2017). Deficits in self-regulation are linked to severe risks, including aggression (DeWall et al. 2007), addiction (Zucker et al. 2011), and psychopathology (Laceulle et al. 2019).

Yet self-regulation seems to be a conceptual wild card: it is as popular as ambiguous and differently understood in many disciplines. The overwhelming body of models and theories of self-regulation calls for an integrative framework that would reconcile various meanings attributed to this term. Such attempts have been already made, thus providing a comprehensive roadmap of the existing discourses around the issue (Bridgett et al. 2015; Inzlicht et al. 2021; Karoly 1993; Lord et al. 2010; Vancouver 2008). Still, the empirical research does not always inform each other and leaves a noncoherent picture of the self-regulation construct (Burman et al. 2015; Eisenberg et al. 2019; Nigg 2017).

The apparent yet most likely dominant reason for the ambiguous meaning of self-regulation is its multiple provenances. While many disciplines have indeed (re)constructed the self-regulation

term, the contemporary understanding seems to consist of two parts, one with origins in cognitive and neuropsychological literature and the other built upon personality research heritage (Malanchini et al. 2019). From the cognitive view, self-regulation largely relies on one's executive functioning: the employment of mental operations, including inhibition, updating, switching, and working memory, as well as their combinations engaged in planning, reasoning, and problem-solving (Diamond 2013; Miyake et al. 2000; Miyake and Friedman 2012). The personality-oriented perspective points to various constructs considered crucial for effective self-regulation. These include self-control, grit, impulsivity, and other – often temperamentally rooted and relatively stable – traits and dispositions.

Importantly, in both those traditions, the dual nature of self-regulation is recognized. Not only deliberate, top-down, and effortful processes constitute one's capacity to self-regulate, but also reactive, bottom-up, and automatic components. Although these two systems have been traditionally described as independent and competing, thus often generating a conflict between temptations and long-term strivings (e.g., Hofmann et al. 2009; Kahneman 2011), they both perform regulatory functions (see, e.g., Evans and Stanovich 2013; Nigg 2017). For instance, in the face of novelty and uncertainty – inevitable when dealing with the possible – more reactive and automatic responses might initiate the self-regulation process. Such a spontaneous reaction can determine whether a person approaches the novel situation or withdraws from the encountered challenge. In other words, an initial response to the emerging opportunity can be marked by overcontrol (behavioral inhibition) or undercontrol (impulsivity), thus focusing attention on or swaying from engagement with the possible. Then, more strategic and deliberate processes – an effortful control of behavior, thought, and affect – may come into play.

Importantly, this is just one example of how self-regulation can unfold over time. The interplay of different self-regulatory mechanisms is much more dynamic and characterized by mutual exchanges. Studies that compared

performance-based (close to the cognitive tradition) and self-report (stemming from personality research) measures of self-regulation demonstrated weak to moderate or even more often insignificant links between these ratings (e.g., Nęcka et al. 2018; Toplak et al. 2013). It suggests conceptual and – most of all – functional distinctiveness of executive functions and personality-oriented aspects of self-regulation. However, despite being separate, both components affect each other and can be mutually influential throughout development (Blair 2016; Blair and Ursache 2011; Howard et al. 2021). It confirms the complexity of self-regulatory processes, with cognitive, metacognitive, affective, and motivational components orchestrated when governing the activity.

From this perspective, it seems crucial not to reduce self-regulation to cognitive abilities or to stable traits rooted in personality or temperament. Instead, a more holistic approach that underlines both dispositional and skill-related aspects of self-regulation and considers the managed activity's dynamic and transactional context seems more fruitful (see, e.g., Frazier et al. 2021; Karoly 1993). With such a broad view, self-regulation of various actions could be described, including short- and long-term, and those with well-defined or rather unspecified goals. This approach seems especially well-aligned for explaining how people realize their creative pursuits: explore the possible and fulfill their creative potential.

Self-Regulation in Actualizing the (Creative) Possibilities

Self-regulation and creative action are often initiated by the failure of well-known, habitual patterns of acting and thinking. This is when the inevitable feeling of uncertainty emerges, which triggers the search for new possibilities (Beghetto 2020, 2021). However, it is also when a goal-oriented approach is being activated, and self-regulatory processes are mobilized (Karoly 1993).

Indeed, when striving for a creative goal, the experience of uncertainty is natural and present from the very beginning to the very end of the

creative process. Usually, people start with a vague idea of what they want to achieve; they formulate a problem, consider possible ways of acting, and anticipate the results. However, through the entire creative process, both goals and the means to attain them are revised, reformulated, and adjusted (Botella 2013; Glăveanu et al. 2013) as new ideas and opportunities emerge (Sawyer 2018). Even when a creative outcome is achieved, it still may be inconclusive (Corazza 2016) – perceived as unfinished, requiring reworking, and open to new interpretations.

The creative process is demanding, and thereby many people do not decide to engage fully in creative activities. There could be multiple reasons behind such a decision, with various motivational factors being emphasized as critical drivers of the decision to act creatively or not. Indeed, regardless of the actual creative abilities and dispositions, one may have little confidence in them or do not perceive creative challenges as worth the effort. When this is the case, one's creative agency – willingness to act creatively and confidence to do so – is insufficient (Karwowski and Beghetto 2019). Similarly, holding attitudes that are unfavorable for creativity, like risk aversion or expecting a negative social response to one's creative attempts, may hold back from engaging in creative pursuits (Beghetto et al. 2021; Ivcevic and Hoffmann 2021).

Therefore, to explore the possible in the actual creative action, a healthy and adequate creative self – built on adaptive creative self-beliefs and positive orientations towards creativity – is needed. Still, the regulatory aspect of the creative self has not been fully explored to date. In what follows, we briefly discuss the nature of creative self-regulation and the mechanisms that most likely constitute one's capacity to initiate, guide, and persevere in creative efforts.

Hot and Cold in Creative Self-Regulation

Creative individuals, particularly eminent figures in science or art, are often perceived as absent-minded, impulsive, and chaotic. While

this stereotype is not completely invalid, it is grossly oversimplified, like all stereotypes. Creative work, particularly when associated with fulfilling long-term goals, be it completing a novel, creating a painting, or composing a symphony, is, after all – a work. It is anything but easy – such work does not happen incidentally; successes do not come without effort and dedication.

Consequently, the analysis of creative self-regulation requires a nuanced perspective that considers different forms and levels of creativity. When creative ideation (e.g., generating ideas for a new game with friends) or solving everyday problems (e.g., figuring out how to create the most original presentation for tomorrow's science class) are considered, self-regulation is likely less critical – or simply centered around a narrow range of control processes – than when long-term actions are fulfilled. In the divergent thinking task or during the brainstorming session, individuals focus on generating many ideas; they inhibit less original ones and use different strategies to create new responses that were not proposed before. Self-regulatory mechanisms engaged here are primarily those of cognitive and metacognitive character. They might include considering an object's properties or decomposing it to reassemble its components (Gilhooly et al. 2007) or introducing changes based on constant monitoring and self-evaluation (Fayena-Tawil et al. 2011; Jankowska et al. 2018).

However, when we consider creativity as the more complex activity that leads to observable outputs, the role of self-regulatory behaviors and strategies grows. As Ivcevic and Nusbaum (2017) explain, long-term activities require revising the goals and subproducts, using adaptive strategies to overcome barriers, and dealing with obstacles. This is precisely why the role of personality-like characteristics increases. These factors allow some people (yet at the same time make it difficult for others) to flexibly adapt to the situation, change their perspectives and plans, manage affective difficulties they face, and the like. Notably, although self-regulatory behaviors are not always used consciously by people who create, successful creators are surprisingly well-disciplined, organized, and indeed – strategic –

when it comes to their work (see Ivcevic and Nusbaum 2017).

At the same time, however, what makes creativity different from all other spheres of human activities is its uncertainty, openness, and multidirectedness. It is relatively straightforward (even if not always easy in practice) to plan, monitor, and evaluate our activity when the goal is well-defined – like losing weight or quitting smoking. But when individuals manage their creativity, the thing becomes tricky. Plans and initial ideas change and evolve, subproducts (e.g., chapters or sketches) vanish, new opportunities suddenly come into play. As the creative process is by no means linear, neither is creative self-regulation. Different phases overlap or even change their order: planning does not always precede generating – sometimes initial sketches and improvised actions lead to the subsequent plans on developing these ideas (e.g., Glăveanu et al. 2013). Consequently, current theories of creative self-regulation accentuate its dynamic character, with cognitive, metacognitive, affective, and motivational components engaged. For the sake of more conceptual analysis, the creative process is sometimes divided into the phases of preparation, generation, exploration, and evaluation (e.g., Botella et al. 2018), so is self-regulation (Rubenstein et al. 2018). Still, the sequential character of creative self-regulation is rather doubtful.

A recent analysis of adolescents' self-regulation during creative projects (Zielińska, Lebuda et al. 2022), as well as an overview of more professionalized creative activity of adults across a range of domains (Zielińska, Forthmann et al. 2022), demonstrated a sound theoretical framework and promising measurement of creative self-regulation inspired by the perspective of self-regulated learning. These analyses identified seven specific sets of behaviors relevant for the preparation, generation/exploration, and evaluation phases in creativity.

When it comes to the preparation phase (forethought phase to use self-regulated learning words), it was found that obstacles expectations, and uncertainty acceptance form adaptive ways of dealing with creative problems at the initial stage. More creative individuals were found to be more

aware of different problems they will meet during their work and obstacles to be managed, yet this awareness does not make them less effective; quite the opposite. In a variety of contexts, it was indeed shown that when people supplement their desired futures – the images of what they want to become or achieve – with more pragmatic views on potential obstacles to overcome, they are more likely to succeed and attain the set goal (Oettingen et al. 2000).

Three factors emerged as particularly important when the activity starts (performance phase). The first, described as the adjusting approach, is associated with flexible ways of dealing with the task to obtain the best results. The second, managing and reframing ambiguous goals – so a tendency to accept and deal with ambiguity – focuses on making the process steps more specific and well-defined with time. The third factor pertains to emotion regulation, mainly when obstacles are more severe than expected.

Self-regulation does not end when the activity is done. The proposed product and steps taken are subjects to self-reflection, often inspiring future initiatives and actions. Two factors identified as relevant for creative self-regulation in this phase are the improving approach, the tendency to improve and do something better next time, and the readiness for sharing – an orientation towards presenting the outcome to others.

Self-regulation makes complex tasks, including creative tasks, approachable. Although there is no guarantee that the individual conducting such actions will eventually succeed, applying self-regulatory behaviors in phases of planning, performing, and evaluating the activity, makes success more likely. Thus, self-regulation is among the elements that translate *what is imagined* to *what is possible*. However, people differ greatly in the effectiveness of their self-regulation. Therefore, what seems particularly important, are different ways of making it more efficient. Such interventional solutions would be particularly welcome in the case of creativity. Previous research confirmed that several training-like interventions effectively develop divergent thinking (Scott et al. 2004) or creative imagery (Karwowski et al. [in press](#)). However, a new and fascinating area of endeavor is to develop similar

interventions that could support people's self-regulation, including creative self-regulation. So far, promising results have been obtained in research on so-called “wise interventions”: focused on well-targeted motivational prompts that strengthen people's self-perception, thereby increasing their performance and well-being (Walton and Crum 2021). A recent study (Zielińska et al. [in press](#)) has also found that this approach might be efficient in building creative confidence and indirectly supporting everyday creativity. Future interventions should take a closer look into the possibilities of strengthening creative self-regulation.

Conclusion

To fully understand how something is possible or not, scholars need to better understand the nuances and conditions of people's activity. As we emphasized in this entry, complex tasks and projects to be conducted effectively require cognitive skills and abilities and the decision to engage individuals' energy into actions and manage these actions well. This is when self-regulation comes into play, focusing on planning behaviors, monitoring progress and potential barriers, and evaluating the effects obtained.

Given that creativity could be considered a perfect case of exploring the possibilities of our potential, the particular focus in this entry was on creative self-regulation. The novelty and uncertainty experienced when pursuing a creative goal make attaining it highly dependent on the solid creative self: personal orientations towards creativity and adaptive modulation of one's engagement. This constitutes the self as both a *source* and a *target* of regulatory processes. Thus, creative potential to be brought into fruition has to be powered not only by a desire to succeed but also by agile governance of the undertaken goal-directed actions.

Some promising attempts to conceptualize creative self-regulation's complex and dynamic nature have been made. Notably, different control mechanisms were identified as particularly vital for guiding creative actions in the preparation phase, during the actual performance, and when reflecting on what has been attained. The set of

factors found beneficial for realizing the creative projects might inspire researchers and practitioners to design tailored programs and interventions that would support people's self-regulation across all stages of the creative process, thus making creative goals *possible* to reach.

Semiotics

Robert E. Innis
Department of Philosophy, University of
Massachusetts Lowell, Lowell, MA, USA

Abstract

What is a sign? Why are there signs? Where do signs come from? How many types and kinds of signs are there? What is the basis for their

classification? What are their respective powers? How do they stand to one another? What are the various uses to which they can be put? Semiotics, the general theory of signs, is the discipline that tries to answer these questions in a systematic and comprehensive way. Semiotics deals with meanings and messages in all their forms and all their contexts. Semiotics takes its name from the Greek word *semeion*, a sign, mark, or token by means of which a thing is known or differentiated from another. Semiotics studies *semiosis*, processes of meaning-making or signification through signs and sign systems of every kind. We are caught up in these systems, and by means of them we interpret our lives and the “worlds” in which we live or desire to live. Semiotics is a “big tent” discipline. Its practitioners and proponents come from related yet different backgrounds and disciplines and have developed different analytical procedures, conceptual schemes, and theoretical focal points. Some have extended the scope of semiotics to the whole range of cultural phenomena that must be interpreted, or reinterpreted, in semiotic terms. Other have developed the area of biosemiotics to inquire into how far down in the realm of living forms one can see semiosis occurring. This entry will show how it is possible to frame these core questions and issues with the help of analytical tools developed by three fundamental figures in semiotics: Ernst Cassirer, C.S. Peirce, and Karl Bühler.

Signs · Semiosis · Language · Expression · Representation · Symbolization · Abstraction

Nature and Scope of Semiotics

Semiotics takes its name from the Greek word *semeion*, a sign, mark, or token by means of which a thing is known or differentiated from another. Semiotics studies *semiosis*, processes of meaning-making or signification through signs and sign systems of every kind (see Nöth 1990; Sebeok 2001). We are caught up in these systems,

and by means of them we interpret our lives and the “worlds” in which we live or desire to live.

In Ernst Cassirer’s *An Essay on Man: An Introduction to a Philosophy of Culture*, we find the following passage:

Physical reality seems to recede in proportion as man’s symbolic activity advances. Instead of dealing with the things themselves man is in a sense constantly conversing with himself. He has so enveloped himself in linguistic forms, in artistic images, in mythical symbols or religious rites that he cannot see or know anything except by the interposition of this artificial medium. (1944, p. 25)

It is within and by means of this diverse artificial medium and symbolic activity that human beings “weave the symbolic net, the tangled web of human experience.” This web is both the product and the generative matrix of the various forms of human possibility and creativity. It makes up the “semiosphere” (Lotman 1990) or “symbol world” (Langer 1967, 1982).

Umberto Eco once wrote that the subject matter of semiotics is “co-extensive with the whole range of cultural phenomena, however pretentious that approach may at first seem” (1976, p. 6). Moreover, he claimed, “signification encompasses the whole of cultural life, even at the lower threshold of semiotics” (1976, p. 46). This lower threshold “pushes meaning down” to the level of the “genesis of perceptual signification” (1976, p. 167), the analysis of which entails a “semiotical definition of the *percepta*” (1976, p. 164) and also, perhaps, of the *manipulanda*, that is, those things that are subject to our “handling” (Tallis 2003). Such considerations make semiotics a “big tent” discipline. Its practitioners and proponents come from related yet different backgrounds and disciplines and have developed different analytical procedures, conceptual schemes, and theoretical focal points (Chandler 2017, Chap. 1; Nöth 1990; Innis 1985).

Roman Jakobson, one of the most important language theorists of the twentieth century, argued that while language is “a purely semiotic system,” semiotics as a general theory must also be able to analytically illuminate such applied semiotic structures as architecture, dress, or the vast culinary forms of culture. As he put it, “any edifice is

simultaneously some sort of refuge and a certain kind of message. Similarly, any garment responds to definitely utilitarian requirements and at the same time exhibits its various semiotic properties.” For Jakobson, “semiotics deals with those general principles which underlie the structure of all signs whatever” (Jakobson 1968, p. 698; cited in Chandler 2017, location 439). Ferdinand Saussure, whose *Course in General Linguistics* became a conceptual resource for an important strand in semiotic or “semiological” research, wrote that one can conceive of a science “that studies the role of signs as part of social life” (1986, p. 15). He proposed calling it *semiology* and assigned it to social psychology. But its task was first and foremost to be the investigation of “the nature of signs and the laws governing them” (p. 15).

In Saussure’s conception linguistics is itself only one part of this general science, although it also became at the hands of others at times a model for it by reason of the centrality of language in human life. Roland Barthes famously wrote, with Saussurian linguistics in the background, that images are “penetrated through and through by the system of meaning, in exactly the same way as man is articulated to the very depths of his being in distinct languages,” since “the psyche itself is articulated like a language” (Barthes 1977, p. 47), a position taken up and developed by the French psychoanalyst Jacques Lacan (2002).

John Dewey in his *Experience and Nature* rightly called language the “the tool of tools, [...] the cherishing mother of all significance” (1925, p. 146), but not in the sense that the signifying powers of the language animal’s offspring – art, myth, religion, ritual, mathematics, political constitutions – are merely derivative and never go beyond the semiotic power and reach of language in the normal discursive or pragmatic sense. This they clearly do, but they grow out of the determining matrix and principles of language. In his *Logic: The Theory of Inquiry* (1938), Dewey went on to claim, anticipating Jakobson, that language can or should be taken in its widest sense to include not just written or oral speech or gestures but “rites, ceremonies, monuments and the

products of industrial and fine arts” such as temples, statues, and looms (pp. 51–52).

C. S. Peirce, one of the founders of American pragmatism and developer of a comprehensive general theory of signs, made a more fundamental claim: “whenever we think we have present to consciousness some feeling, image, conception, or other representation, which serves as a sign” (1931–1958, CP 5.283; cited hereafter as volume and paragraph) and as a result “all thought . . . must necessarily be in signs” (CP 5.251). Thinking about ourselves has to be thinking *in* and *about* signs, and language is the ultimate medium in which this is carried out. Peirce wrote:

For thinking is a kind of conduct, and is itself controllable, as everybody knows. Now the intellectual control of thinking takes place by thinking about thought. All thinking is by signs; and the brutes use signs. But perhaps they rarely think of them as signs. To do so is manifestly a second step in the use of language. (CP 5.534)

This second reflective step, however, reveals sign systems that have a different logical form from language even if they would not be possible without it: artistic images, music and dance, mythical symbols, religious and non-religious rituals, and so forth (see Langer 1942, 1953; Innis 1985, 2009).

Signs in all their forms function as mediating devices linking an organism and the world, both natural and social, with which it is interacting. By means of these signs of different types and modes, we grasp, are grasped by, and express the affective, practical, and conceptual significances in the spiraling circuits of engagement with our natural and cultural environments. Thinking in signs makes possible, but does not guarantee, our becoming explicitly aware of the determining role signs and sign systems play in the conduct of our lives. We need to know not only what makes them possible, but *what they make possible*.

Cassirer affirmed “*as the fundamental feature of all human existence*, the fact that man is not lost within the welter of his external impressions, that he learns to control this sea of impressions by giving it *ordered form* . . . a unique productivity . . . the *objectification*, the *apperception*, of the

ground of all theoretical, aesthetic, and ethical creation of form” (1942, pp. 22–23).

Semiotics has as one of its central tasks, overlapping with philosophy, to determine the nature of the “ground” out of which the creation of this artificial medium, the symbolic net, the realm of ordered form, arises and is supported. In line with the theme of this volume, this article will not be a survey of semiotics but the *exemplification* by a kind of “method of rotation” of how some fundamental semiotic analytical tools help, in different but complementary ways, to frame the “ground” of the possible.

Functional Circles and Form Worlds of Meaning

Cassirer saw in theoretical biologist Johannes von Uexküll’s (1934, 1940/2010) schema of a “functional circle” or “functional cycle” (*Funktionskreis*) a powerful model for characterizing the life activity of each type of organism, including the human organism, in its *Umwelt* or species-specific environment. Uexküll contended that each organism, by reason of its structure, functioned within a “circle” or “cycle” of recurring activities. Such a circle is structured by a *receptor system* within which the organism “marks” or “apprehends” cues or “distinctive features” in its perceptual field and an *effector system* within which it responds into a motor field or space of action of some sort. Those fields thereafter carry the patterned results of this effective responding, and the organism then responds perceptually and effectively to them in a recurring cycle of activities. These worlds, Uexküll showed, are the species-specific perceptual and pragmatic *meaning-spaces* of organisms, a central concern of what is now biosemiotics (see Hoffmeyer 1993, 2009; Favareau et al. 2012; Kull 2015).

The human *Umwelt*, however, Cassirer points out, is not a functional circle of recurrent limited patterns but the building of a dynamically open *symbolic system* made up of different types of signs and sign-configurations. This system does not just quantitatively enlarge our perceptual-motoric functional circles but qualitatively

changes them. This symbolic system, nevertheless, has its roots in the development of enlarged capacities of the symbolic animal's body-based sensory and effector systems (Deacon 1997; Tallis 2003, 2010). It is a *metabasis eis allo genos*, an emergent system not reducible to, but nevertheless incorporating, its biological antecedents. The central lesson for semiotics of Uexküll's concept of a functional cycle, according to Cassirer, is that "reality is not a unique and homogeneous thing; it is immensely diversified, having as many schemes and patterns as there are organisms" (1944, p. 23). These schemes and patterns determine what is both physically and semiotically possible for organisms.

Cassirer's model of the symbolic net (1924, 1925, 1929) is a permanent resource and model for semiotic analysis of the possible that joins universality with specificity (Lofts 2000). It is based on a triad of "form worlds" arising out of progressively more *objectifying* activities rooted in what Cassirer called the "original attitudes and formative modes of consciousness" (1929, p. 57). These modes, making up the semiotic triad of expression (*Ausdruck*), representation (*Darstellung*), and pure or formal signification (*Bedeutung*), underlie and are embodied in the human systems of signs that make up the symbolic net of cultural forms. These modes are not sequential. Cassirer's triad of modes is a heuristic structure for analyzing how experience with its form worlds is structured from a semiotic point of view.

The systems of signs in which we dwell and from which, as Peirce argued, we cannot escape make up our "exosomatic body," a semiotic body. Elmar Holenstein, writing about structuralist semiotics, remarked that it showed "the root-like attachment of the world's subjective constitution to sign systems" (1976, p. 5). Michael Polanyi showed how the acritical assimilation of and indwelling in sign systems is "fraught with the roots it embodies" (1966, p. x). The semiotic body is clearly dependent in certain ways on the natural body and its powers that are proper to the human type of being. But Cassirer's analysis shows it is precisely the emergent self-creating reality of our articulated sign systems that

transcends or breaks the relatively closed functional circles of non-human organisms and builds another circle, the ever widening gyre of human semiosis, rooted in the triad of expression, representation, and pure signification as the informing modes of consciousness. They make up the dimensions or open fields of possible meanings that can never be separated from their roots in the conditions of our natural and semiotic bodies.

Cassirer characterizes the "primary form of consciousness" (1929, p. 107) as the domain of *expression*, the semiotic mode in which the "original face" of objects (1929, p. 70) is encountered, a "vast diversity of original physiognomic characters" (1929, p. 68) with "physiognomic individuality" (1929, p. 69). The psychology and phenomenology of perception has explored this dimension of experience in classic works as have the works of the cultural anthropologists and students of pre-history. This original face is not of "things" but of "definite modes of appearing" (1929, p. 73), experienced qualities to which are applied such words as luring, repellent, minatory, mysterious, smiling, eerie, and so forth. The affective stratum of human experience is pregnant with significances that elude discourse but not articulation. The history of culture shows humans to be extraordinarily sensitive to these significances, even in the pre-historical period of humanity's development. Humans have *objectified* these significances, from time immemorial, in materials and actions of every sort: visual forms, ritual acts, mythic narratives, music, word magic, and so forth (1925). This is Cassirer's domain of *expressive signs*, both natural and cultural, reaching high levels of sophistication in both technique and content in the arts.

Cassirer characterizes the formative mode of *representation* as the movement to "richer and higher forms of experience" (1929, p. 107), the achieving of an "entirely new level of consciousness" (1929, p. 111). The primary form of this mode is human language, as opposed to the calls, signals, and proto-symbols permeating the pre-human world. Language constitutes the core power engine of the human symbolic system. What makes it possible and what does it make possible? Cassirer attributes this achievement to

our being able to abstract from a “formed total intuition” or Gestalt of some sort a “factor” that is “taken as representative of the whole” (1929, p. 114). The antecedent expressive whole presented as “the immediate face of things” (1929, p. 110) becomes a “thing,” indeed a *type* of thing, with its attributes, although it does not lose its expressive quality. Attributes become the “representatives” of the thing, allowing it to be a member of a class. The attributes *stand for* and *make present* the thing in and to consciousness. This standing for relation is the fundamental feature of signs. Language stabilizes and extends this interpretive power to grasp the “as-structures” of things.

Cassirer’s analysis shows us, however, that *presentation*, proper to expressive consciousness, and *re-presentation*, through and in the abstraction of perceptually selective and variably motivated defining features, are indissolubly joined together. The development of the systems of presentational symbols in the arts out of their historical groundings in ritual and myth is an achievement rooted in language. Humans, as those animals that “divide their voices” in speech, are also those that divide the material perceptual world itself. Out of such materials, we construct “symbolic forms” that embody unending ranges of felt significances. Just as human languages carry or embody “natural world views,” so it is the break in experiential immediacy effected by language that enables the creation and recreation of experienced worlds in the arts. According to Cassirer the modes of both expression and representation are bound to the perceived world which can be “visualized” or grasped in images or image-schemas of some sort. But, as sign systems, they are also marked by an unending semiotic productivity by reason of their inextricable connection to the open temporal flux of experience itself that is taken up and woven into the symbolic net.

Cassirer distinguishes a third formative mode that he calls “*pure signification*” (*Bedeutung*). This mode goes beyond the “natural world concept” of the two “prior” modes which deal, as he put it, with “configurations” (1929, p. 283) of greater or lesser stability and fixedness. These are “definite totalities of meaning” (1929,

p. 286), tied as they are to affective apprehension and perceptual articulation through language and affect-laden image-based sign systems. Pure or formal signification gives rise to a “new kind of object” (1929, p. 320) which is not the result of perception-based conceptual syntheses. Cassirer importantly notes that this move to the “higher potency of the discursive” (1929, p. 288) “does not create a break in the totality of knowledge—it continues a basic trend as an emergent property of human organisms, which already proved to be at work in the first stages of sensory, perceptual knowledge” (1929, p. 307).

This basic trend is the power that sign systems have of differential articulation or segmentation of the experiential continuum, until one arrives at differentiation and constructive creation of the semiotic medium itself as it moves toward systematic formalization or axiomatization. The objects of “pure signs of signification” (1929, p. 285, see also 1910/1923) are no longer classes but relational patterns and laws. This is the world of mathematical physics and of the formal sciences, but not that of the observational sciences, although even they are subject to differing degrees of formalization and systematization. Such a shift toward pure signification is more evidence of the fundamental semiotic principle that “no being is tangible or accessible except through meaning” (1929, p. 299). The strangeness of the purest forms of this world view comes from the move toward ever more universal symbols and toward a view of the world “from the standpoint of no one” (1929, p. 478). Cassirer admits, however, that it is impossible to step over one’s shadow. This is a problem that has vexed scientists and philosophers for more than a century by reason of the paradoxes arising out of the tension between observation and theory in physics and crises in the foundations of mathematics and logic.

Cassirer’s semiotic framework also allows us to see the links, indeed even parallels, between the distinctively semiotic form worlds of culture and the form worlds arising from the exploitation and transformation of materials, the world of “technics” or technology and the differentiation of the spatial frames of life into the mythical, aesthetic, theoretical, corresponding to the triad of formative

modes of consciousness (Cassirer 1930, 1931; Innis 2002, Chap. 6). Cassirer shows that the transformation of materials, and our own self-transformation by reason of our engagement with materials, follows the dynamic trajectories of technics from the early participatory, mimetic, or even magical phase, through an intermediate analogical representational phase based on “organ-projection” modelled on the body, to the abstract formal technologies, rooted in the dimension of “pure signification,” exemplified in the information revolution (see Innis 2002, Chap. 6). Our semiotic bonds to the world become materially effective through their enabling, for weal or woe, of materio-technical practices in which we are embodied (Bardt 2019; Innis 2002, Chap. 5). The effects of semiosis spread over the human world as a whole, weaving it together but also tearing it apart and reassembling it in new ways by critically projecting fields of the possible: possible fields of new self-interpretation, possible fields of new semiotic effects, and new worlds of artifacts that confront us not just with their functional fields but with their at times ominous messages, as the splitting of the atom has shown.

Signs and the Free Water of Consciousness

Another indispensable way of determining the general principles of semiotics that frame the grounds of the possible has been developed by Peirce, whose writings have spawned cascades of commentary and extension (Jappy 2020). Peirce offered a striking image of consciousness, quite different at first glance from Cassirer’s rather laconic, though dynamic, notion of formative modes. He writes:

I think of consciousness as a bottomless lake, whose waters seem transparent, yet into which we can clearly see but a little way. But in this water there are countless objects at different depths; and certain influences will give certain kinds of those objects an upward impulse which may be intense enough and continue long enough to bring them into the upper visible layer. After the impulse ceases they commence to sink downwards. (CP 7.547)

Following a long philosophical tradition stretching back to antiquity, Peirce distinguished three categories of consciousness:

First, feeling, the consciousness that can be included with an instant of time, passive consciousness of quality, without recognition or analysis; second, consciousness of an interruption into the field of consciousness, sense of resistance, of an external fact, of another something; third, synthetic consciousness, binding time together, sense of learning, thought. (CP 1.377)

These modes, called in other contexts “*primisense*,” “*altersense*,” and “*medisense*,” are not to be thought of as sequential any more than Cassirer’s were meant to be, although there is an intrinsic ordering in their pattern. Peirce referred to them as “constant ingredients of our knowledge” due to “congenital tendencies of the mind” (CP 1.374). It is within them, as ultimate elements of consciousness or “faculties of the soul,” that Peirce locates signification and the creative functioning or play of signs in human life. They are clearly the potencies informing those “certain influences” that bring “certain kinds” of objects forward into light and stabilize them in systems of signs.

Peirce contended in a rich passage (CP 1.381) that “... every kind of consciousness enters into cognition” – and by extension into semiosis, since for Peirce all cognition is defined as sign processes or forms of semiosis. Feelings “form the warp and woof of cognition ... the will, in the form of attention, constantly enters,” but “cognition is neither feeling nor the polar sense.” It is “consciousness of process, and this in the form of the sense of learning, of acquiring, of mental growth.” This process cannot be “contracted into an instant.” It is “the consciousness that binds our life together. It is the consciousness of synthesis” (CP 1.381). This process of synthesis, Peirce holds, is supported and structured by pervasive processes of signs growing out of signs, a process of infinite semiosis. The combinatory power of signs generates new possibilities of interpretive syntheses, including the interpretive syntheses of self-reflection and self-criticism (see Innis 2019a, b for applications).

Peirce defines what a sign is and does with deceptive generality:

A sign, or *representamen*, is something which stands to somebody for something in some respect or capacity. It addresses somebody, that is, creates in the mind of that person an equivalent sign, or perhaps a more developed sign. That sign that it creates I call the *interpretant* of the first sign. The sign stands for something, its *object*. It stands for that object, not in all respects, but in reference to some sort of idea, which I have sometimes called the *ground* of the representamen. (CP 2. 228)

On the basis of this characterization, Peirce proposes three analytical paths for semiotics. A grammatical path determines what makes it possible for any sign to “embody any *meaning*.” The logical path examines the conditions of how any sign is linked to its *object*. The rhetorical path seeks to establish how “one sign gives birth to another, and especially one thought brings forth another” (CP 2.227–9), that is, the generation of interpretants, the “thought-signs” by means of which we access the object referred to by, and determining, the sign.

For present purposes, framing the semiotic grounds of possibility, the principal focus will be on (a) Peirce’s classic schema of how signs are related to their objects, a logical relation, and (b) the consequent differentiation of interpretants, what Peirce called “the proper significate effects” that each type of sign gives rise to, or ought to give rise to, in the life of interpreters.

The logical relation between signs and objects yields three main classes of signs: icons, indices, and symbols.

An *icon*, in Peirce’s formulation, is a “sign which refers to the Object it denotes merely by virtue of characters of its own, and which it possesses, just the same, whether any such Object actually exists or not” (CP 2.246). Iconic signs such as images, diagrams, models, algebraic equations, and so forth refer to their objects, which can be purely “internal,” as in works of the imagination, by reason of their *material quality*. The icon, which Peirce also called a *qualisign*, a sign of quality, is linked by association and by some sort of “resemblance” to what it is “about,” that is, what is *presented* in and by the structure of the iconic sign itself. It embodies a quality and is a

correlate of feeling, grounded in the first mode of consciousness and its generative powers of constructing images, both internal and external, that stabilize and schematize the subjective world of the flux of feeling. Icons can embody or make perceptible, by the complex material qualities of their elements, forms of feeling of every sort, as the history of art shows as well as the rich world of mythic imagery and rituals (Langer 1953; Innis 2009).

An *index* is a “sign which refers to the Object that it denotes by virtue of being really affected by that Object” (CP 2.247): traffic signals, marks on trees on hiking paths, footprints in the snow, a blush, but also paradigmatically the pointing finger or furtive glance, or demonstrative and personal pronouns (Tallis 2010). Indexical signs, whether natural or constructed, denote or draw attention to something existent to which it is linked, the second Peircean mode of consciousness. Without an object there would be no index. They mediate adjustments, whether by pragmatic action, functioning as signals, or in perception, functioning as criterial properties of an object or situation. Indices belong to the world of *resistances*, controlling attention to their objects.

A *symbol*, in Peirce’s specific use of the term, is a “sign which refers to the Object that it denotes by virtue of a law, usually an association of general ideas, which operates to cause the Symbol to be interpreted as referring to that object” (CP 2.248). The “law” is the principle of language in its generalizing function. A symbol arises out of a creative synthesis of reducing a multiplicity of objects to a unity and that most fateful of all acts – giving names to things, also new names, and combining them on the basis of acts of abstraction that both divide the experiential field into units and group these units into classes and relations of different levels of generality. Symbols are grounded in the third mode of consciousness.

The upshot of Peirce’s distinctions, which are widely accepted, is not that these types of signs run on separate tracks, but that the human level of sign use, the distinctively *symbolic* level paradigmatically illustrated in language, incorporates within the free water of consciousness three intertwined and simultaneously operating

semiotic modes. Just as every mode of consciousness enters into cognition, so every mode of consciousness enters in some way into semiosis on the distinctively human level, the level of “synthetic consciousness, binding time together, sense of learning, thought.” About this dynamic interrelation, Peirce wrote in a provocative passage:

Symbols grow. They come into being by development out of other signs, particularly from icons, or from mixed signs partaking of the nature of icons and symbols. We think only in signs. These mental signs are of mixed nature; the symbol-parts of them are called concepts. So it is only out of symbol that a new symbol can grow. *Omne symbolum de symbolo.* (CP 2.302)

The sign systems in which we live and whose powers we both utilize and are subject to work in concert together. They enable new forms of feeling, fields of action, and systems of thinking by acts of what Peirce called *abduction*, the risky *seeking of signs* to articulate the senses of a world in constant development. The meanings that signs give birth to or open up in both their creators and their interpreters are *interpretants*, the proper significate effects of the sign-configurations that capture in various ways the various senses of the world. The notion of an interpretant is an indispensable component of an analysis of the general structures governing the possible effects of signs.

Peirce proposed various alternative schemes of interpretants. One scheme divides interpretants into immediate, dynamic, and final. Another scheme divides interpretants into emotional, energetic, and logical (Nöth 1990, pp. 43–44). Both schemes mirror Peirce’s schema of modes of consciousness either implicitly or explicitly, but they foreground or emphasize different aspects.

As to the first scheme, Peirce describes the *immediate* interpretant as “the Quality of the Impression that a sign is fit to produce, not any actual reaction” (1998, p. 499; CP 8.315). Other formulations define it as “the total unanalyzed effect that the Sign is calculated to produce” [...], or “the peculiar Interpretability” of the sign “before it gets any Interpreter” (Hardwick and Cook 1977, pp. 110–111). The *dynamic* interpretant is “the

direct effect actually produced by a Sign upon the Interpreter of it, [...] that which is experienced in each act of interpretation and is different in each from that of any other” (Hardwick and Cook 1977, pp. 110–111). The *final* interpretant is “that which would *finally* be decided to be the true interpretation if consideration of the matter were carried so far that an ultimate opinion were reached” (1998, p. 496; CP 8.184) or “the one Interpretative result to which every Interpreter is destined to come if the Sign is sufficiently considered” (Hardwick and Cook 1977, p. 111). The underlying schema here is Peirce’s categories of consciousness, the triad of feeling of quality, reaction, and thought.

As to the second scheme, Peirce admits as a “provisional assumption” that it is “pretty near to the general truth” that an interpretant “is, at least, in all cases, a sufficiently close analogue of a modification of consciousness” (1998, p. 411). The *emotional* (or *affective*) interpretant of a sign is the modification of the very “tone” or “distinctive feel” of consciousness. It is the modification or constitution of a *resultant feeling* by a sign whose object is a *quality*, that is, an iconic sign. The *energetic* interpretant is a *felt interruption or directing of attention* by a sign whose object is some *resistant* other, that is, an indexical sign. Peirce’s *logical* interpretant, paradoxically, is not determined by a sign’s being determined by an “object” already existent. Peirce holds that the logical interpretant does not correspond with any kind of object but rather with an “idea” – the “thing-meant” – that both determines and is determined by the sign to which it is linked. This is clearly the case in both the normal and creative use of language, where thoughts are continuously “translated” or “unfolded” into other thoughts and thoughts about thoughts and so on as experience continues to outrun the linguistic schemes in which it is captured.

Peirce’s semiotics sees semiosis as resulting in a “series of successive interpretants” without end (CP 2.303). Thinking in signs is an essentially dialogical process, whether the dialogue partner is another person or oneself. Peirce contended, following a long line of philosophical reflection and confirmed by Vygotsky and many others in

classic studies, that “thinking always proceeds in the form of a dialogue—a dialogue between different phases of the *ego* – so that, being dialogical, it is essentially composed of signs” (CP 4.6). The engendering of interpretants by signs is the unending progressive unfolding of possible interpretive construals of experience and, to extend what Peirce said about the logical interpretant, “must, therefore, be in a relatively future tense” (1998, p. 410).

This future tense of human semiotic systems quite generally is the source of their ability to capture the spiraling resting places and transitions in the flux of experience that, as William James wrote, grows by its edges. Experience is haunted by that sense of an “overmore” or of an indefinite open that is rendered intense in unending objectifying processes of semiosis. The great contribution of a Peircean semiotics is to show how the action of signs sets us in motion on all levels of our existence. It frames in creative fashion central universal principles of semiotics that establish how the human use of signs generates by its own nature signs of possibility, which we become aware of in what Peirce called that “second step” in the use of language where it turns explicitly upon itself and in the process brings itself to mind in its semiotic reality.

Language, Abstraction, and Diacrisis

Karl Bühler offers such an analytical framework in his classic work, *Theory of Language* (1934), which examines the paradigmatic special place of language in exemplifying and revealing general principles governing sign systems. Bühler is most famous by reason of his organon-model of language that diagrams the constitutive elements of a “speech event” Fig. 1.

Bühler explains the import of this model in a compact gloss:

The circle in the middle symbolizes the concrete sound phenomenon. Three variable moments on it are capable of raising this phenomenon in three different ways to the rank of a sign. The sides of the drawn-in triangle symbolize these three moments. The triangle encompasses, in one

Semiotics, Fig. 1 Organon-model of language

respect, less than the circle (the principle of abstractive relevance). In another direction, however, it surpasses the circle, in order to indicate that the sensibly given constantly experiences an apperceptive enlargement. The multitude of lines symbolizes the defined semantic relations of the language sign. It is a *symbol* by reason of its being coordinated to objects and states of affairs; a *symptom* (*Anzeichen, indicium*: index) by reason of its dependence on the sender, whose interiority it expresses; and a *signal* by reason of its appeal to the hearer, whose outer or inner behavior it directs just as other communicative signs do. (1934, p. 28)

The triad of signs composed of *symbols*, *signals*, and *indices* is correlated with the three semantic functions of *representation*, *appeal*, and *expression*. The focal point of Bühler’s model is the analytical power of the notion of *apperceptive enlargement of the sensibly given* material sign-configuration as the result of *abstraction*.

The *expressive* function carried out by the *symptom/index* is a feature attached to its source, which in Bühler’s model of a speech event is assimilated to a “sender.” But such a notion can clearly be extended from the realm of a “toned” speech event to the “expressive face” of anything experienced, whether object or situation, their “material quality.” The *appellative* function carried out by the *signal* effects a steering of inner

and outer behavior of the perceiver. The signal's source clearly need not be an intentional sender but features of any environment, natural or social, in which we act and which steers or even controls our behavior. Bühler (1934, p. 34) notes that the antecedents of these functions on pre-human levels are found in Uexküll's notions of "perceptual signs" (*Merkzeichen*) and "effector" or "operative signs" (*Wirkzeichen*).

Bühler points out that the ways signs are differentiated from one another by diacritical markings model their semiotic powers to effect differentiations in the world and thereby carry information. Diacrisis is the conceptual core of the *principle of abstractive relevance*. It is exemplified in phonology's fundamental distinction between a phone, the physical or tonal reality of a word, studied by phonetics, and a phoneme, which is phonology's concern:

Phonemes are sound marks in the word's tonal reality and in every word they can be counted. But the word-image is also Gestalt-like, it has a tonal face or aspect, that also changes like a human face in the changing course of the expressive or appellative function. (1934, p. 258)

In the *representational* function, only the sound marks necessary for identifying the word as *this* word are *relevant* for linking it to its object. Words are symbols, free creations, not copies of their objects. The naming activity of words is not systematically dependent on their tonal faces. The identification of what the word itself is, across all tonal or accentual variations, involves abstraction of "sound marks," just as identification of objects of experience as *these kinds* involves abstraction of their defining features:

Phonemes belong to the class of marks, properties, criteria, notes: they are sound properties on the tonal picture of the world and constitutes the correlate to the properties of things, which we have known from time immemorial in logic and have characterized as marks or, in Latin, as 'notae.' (1934, p. 278)

Phonology is rich in implications about the linking of perception and symbolization in the human functional circle:

The linguistic fixating and grasping of perceived states of affairs is prepared and rooted in the processes we are accustomed to calling 'perceptions'

and to separating off in an unjustifiably rigorous way from a 'following' linguistic apprehension . . . The orientational instrument of human language which is produced in linguistic intercourse potentiates what the natural signals and symptoms accomplish, which we derive through perception from things and our speech partners and to which we are indebted. (1934, p. 252)

Diacrisis and abstraction mark every level of our meaning-filled interactions with the world in continual processes of *marking differences*. Perceptual segmentation and classification both ground and are taken up into our language schemes, which are not laid over experience as a veneer. There is a constant mutual adjustment of perceptual clues and sign systems of various sorts since experience outruns our ability to catch it in our symbolic nets. Indeed, these symbolic nets, seen by Cassirer and Peirce as "free creations of the spirit," themselves generate new experiences by exploiting their semiotic potentialities and interrelations.

This complex process of mutual adjustments and exploitation is the generative matrix or ground of novelty and possibility of discovery. Polanyi, whose great chapter on articulation is indebted to Bühler, (1958) writes:

To classify things in terms of features for which we have names, as we do in talking about things, requires the same kind of connoisseurship as the naturalist must have for identifying specimens of plants and animals. Thus, the art of speaking precisely, by applying a rich vocabulary exactly, resembles the delicate discrimination practised by the expert taxonomist. (p. 81)

The experienced limitation or inadequacy of a classificatory scheme can lead to the discovery and development of novel classificatory schemes even, and especially, for ourselves. Charles Taylor (2016) writes that naming the basic dimensions of our lives, like pride and anger, is not like naming a toothache: "We develop a rich vocabulary of reasons and occasions for pride, anger, and the rest. And thus, these basic words are foundational to the shape of meanings for us, rather than reordering this shape" (p. 200).

Moreover, the latent predictive power of new concepts and classificatory schemes can "run ahead" of experience and lead us to look for

novelties previously unnoticed in the flux of experience. The formalized symbol systems of mathematically dependent research programs have many instances of this. The rich image-configurations in the various art genres, no matter what their medium, capture in the organization of their material forms the multidimensional significances of ongoing experience and create or project in new image-configurations novel forms of experiences.

Summary Conclusion

Semiotics shows us how we put ourselves not just into words but into all those ordered forms – images, rituals, narratives – that make up the symbolic web we are constantly weaving and in which we have irreversibly entangled ourselves. The productive logic of human semiotic creativity spins out dynamic open fields of diverse possibilities of articulating the senses of the world and of the very shapes of meanings that our lives are to take. Articulation of the senses of the world is not a purely designative or representational process that leaves the world or ourselves unchanged. John Dewey wrote about language, Jakobson’s “purely semiotic system,” that it is not like a pipe conducting water. Such is the case with the panoply of human sign systems that grow out of the language animal’s power to embody its meanings in other ordered forms (Langer 1942, 1967; Stenner 2017). Neither language as a discursive form nor the domain of presentational forms that capture in affect-laden images the felt significances of experiences merely passes on “perceptions, sentiments, and thoughts which are complete prior to language” (1925, p. 169). Dewey is right to claim that “the heart of language is not ‘expression’ of something antecedent, much less expression of antecedent thought” (1925, p. 179). But this is also the “heart” of human forms of semiosis: the unending production of symbolic forms that make up the symbolic web that enables us to have these perceptions, sentiments, and thoughts in the first place as something distinctively human.

Serendipity

Wendy Ross

Department of Psychology, Kingston University,
Kingston, UK

Abstract

Serendipity is a fortuitous accident; the exploitation of luck by a prepared mind. It is a framework for understanding how luck becomes actualized through human activity. It is widely studied across domains as varied as philosophy, information studies, and innovation research and is most often cast as having a role in the uncovering or generation of new ideas by provoking insight through unintended and unplanned bisociation. Serendipity has been credited as a key component of various inventions, creative inspiration, or unlikely yet fortunate happenings with varying degrees of

engagement with its relational ontology. It is thus an integral part of any understanding of the possible because it provides a bridge from the possible to the actual. This entry will define the key types of serendipity and the models which can be used to understand it before examining the evidence suggesting there are differences in personality and environments that may be more facilitative of serendipitous occurrences.

Keywords

Serendipity · Accident · Luck · Problem-solving

When we consider the possible (i.e., what could be and what could have been), it is rare that we do so without invoking luck. In lay terms, luck is often the magic ingredient that bridges the possible and the actual: the element beyond human control that allows the potential possibles to become concrete actuals. This applies when we consider possible pasts as well as possible futures. We wish people luck when they set off to pursue an unknown possible, and we will often assign luck a significant role in shaping the present from the many possible paths that could have been taken. Any model of our understanding of uncertainty and possibility would be poorer without a consideration of the role of luck. However, luck is by its nature arbitrary and unreliable; it resists theorizing or empirical investigations (de Rond 2014). Moreover, it is inert until it is enacted. Perhaps a better conception of the role of chance relies on both contingent luck and personal attributes (e.g., Austin 1979). It is here that the framework of serendipity is useful to understand this emergent interaction. Serendipity is closely related to luck and in the popular lay understanding is used synonymously with no more than good fortune, but a more precise definition is a mixture of both “accident” and “sagacity”. This addresses the arbitrary element of luck. Rather than being simply random happenstance, serendipity becomes a form of transactional luck; a relational phenomenon emerging from a person, a time, and a place.

Definition

The word serendipity was coined by Horace Walpole in his report of the story *The Three Princes of Serendip* where the princes made “discoveries by accident and sagacity.”¹ It has fallen in and out of fashion since 1754 but in 2000 was voted the UK’s favorite word (Ezard 2000). While Walpole coined the word, he obviously did not invent the concept. Furthermore, a pure definition is still elusive, and the boundaries of serendipity are somewhat elastic. This is exacerbated by the story of the three princes that Walpole used to illustrate the new word. This story arguably does not actually reflect his own definition, that is, “making discoveries, by accident and sagacity, of things which they were not in quest of” (cited in Merton and Barber 2004, p. 2), rather the princes’ discoveries could be more clearly put down to a form of intelligent abductive reasoning. Merton and Barber (2004) suggest this word has subsequently functioned as a cipher, allowing writers the opportunity to rewrite definitions to reflect their own preconceptions. However, despite the lack of clarity, the various definitions found in the literature converge on a fundamentally relational concept. There are normally three integral facets: environmental, personal, and temporal. Serendipity involves the right person in the right place and, crucially, is conceived of as a process operating on different timescales rather than a single occurrence. Finally, serendipity is only serendipity if it is recognized as such (Copeland 2017; de Rond 2014; McCay-Peet et al. 2015).

Indeed, from its inception serendipity has been seen as this combination of luck and personal properties. From Walpole to Louis Pasteur’s “le hazard ne favorise que les esprits préparés” (cited in Van Andel 1994, p. 163), writers on serendipity emphasize its dual nature with varying degrees of poeticism. Shulman (2004, p. xiv) suggests it is “a process hovering ambiguously between the [...] incisive mind and the wheel of fortune,” and

¹For a summary of the most cited story from *The Three Princes of Serendip*, see Van Andel (1994, p. 632).

Copeland (2017, p. 1) describes it as being “at the intersection of chance and wisdom”. In all definitions, the serendipitous process emerges from an interplay of external and internal factors, and, crucially, both are necessary. Material and social worlds are dynamically entwined and produce a rich array of possible perceptions and action affordances. The fortuitous and felicitous qualities of some of these possibilities are the main study of serendipity.

It is this relational nature that differentiates it from random chance and mere accident (Foster and Ellis 2014). de Rond writes to “equate serendipity to chance is to unravel but part of a far more promising plot” (de Rond 2014, p. 342). Schulmann exemplifies its relational and temporal nature in his introduction to Merton and Barber (2004) with the tale of Robert Barber being drawn to the word serendipity while reading the dictionary looking for another word. This tale is only complete when we realize that he came across the word several months previously and yet did not pick up on its properties. It was only when Barber was attuned to the concept and open to exploring its implications that it became important to him. A prepared mind is not constant, rather it is temporally contingent. Luck is useless without the right person (or organization) at the right time to capitalize on it (Cunha et al. 2015). A person cannot create serendipity on her own and neither can an environment, however full of potential it may be. Serendipity, then, is contingent on the interaction between the environment and the person and thus requires a truly systemic way of regarding human behavior.

Types of Serendipity

While it has been widely acknowledged in passing, serendipity has yet to be the focus of a mature and systematic research program which characterizes other fundamental concepts such as creativity. While there has been a steady increase in research over recent years, there is a somewhat disjointed theorizing about serendipity; there are almost as many types of serendipity as models

describing them (Van Andel describes 17 serendipity patterns drawn from his extensive collection), and serendipity as represented in the research literature is heterogeneous and fluid. This is in part an inherent characteristic of the concept: it arises from an unplanned interaction between person and environment and will, therefore, be inconsistent and complex. It seems unlikely that a phenomenon which is more often used as a dumping ground for uncertainties and which is inherently unpredictable would yield a clear definition.

However, there is a general consensus converging on four basic types of this multifaceted phenomenon. They have most recently been categorized by Yaqub (2018) using the names of prominent serendipity theorists in relation to scientific discoveries, and the categories he proposes broadly reflect those addressed by other writers such as de Rond (2014). These four types vary along the dimensions of the purpose of search undertaken and the nature of the eventual solution: A search can either be planned or unplanned and can yield the solution to the existing problem or a novel one.

First is pure Walpolian serendipity, in which investigators searching in one problem space make a discovery in a different problem space. Yaqub gives the example of the discovery that *sildenafil citrate*, which was being trialled as a cure for angina, also worked as a cure for erectile dysfunction. Second, a targeted search which finds the solution in the same problem space but through an unexpected route. This is described by Yaqub as Mertonian serendipity. de Rond exemplifies this sort of serendipity by the steps that led Watson and Crick to identify the double helix. External triggers (both people and things) enabled them to solve the original problem but in a serendipitous manner. This type of serendipity is sometimes referred to as pseudoserendipity (Roberts 1989) to distinguish it from pure unsought findings. However, it has been recently argued that if we shift the focus from the problem solution to the problem as being the method of solving the original problem, then this distinction between pure and pseudoserendipity is less clear (Arfini et al. 2018).

Third is finding the solution of a pre-existing problem when there is no particular aim to solve any one problem (Bushian serendipity). Yaqub gives the example of Wells who noticed a man who had injured his leg while under the influence of laughing gas and who felt no pain, an observation which triggered the use of laughing gas as an anesthetic. Finally, an untargeted research program may lead to an accidental discovery which only becomes realized in the future. In this case, neither the problem nor the solution exists at the moment of discovery. This is Yaqub's Stephanian serendipity, and he illustrates this with the example of Benedictus who discovered that a chemical mix resulted in a thin layer over the glass in a flask stopping it from shattering. This accidental discovery later became the basis for safety glass.

Of course, actual examples of discovery and innovation are rarely able to be neatly parcelled, and the boundaries between these categories are fluid. What is important to note is the unexpectedness of the discovery across all four categories. Whether the actual discovery or the method used to reach that discovery, serendipity involves unanticipated and unplanned actions. As Copeland (2017) argues, it is impossible to announce in advance that there is going to be a serendipitous moment; by its very nature, serendipity is unplanned and unexpected. It is also iterative: recognition of serendipity leads to changed behavior which consolidates the serendipity (McCay-Peet and Toms 2015). This unexpected nature points to an uncovering through chance of other, unconsidered possibilities.

Serendipity taxonomies classify serendipity not solely in terms of the event trigger, but in relation to the preceding events and the activities of the person. Serendipity is thus temporally relational – it is contingent on past and future categorization and varies according to these. The same event, if it solves a problem already posed, is considered to be a different sort of serendipity than when it suggests a solution to a non-posed problem. In other words, the same event would be categorized differently depending on the program of problem-solving that had led up to it and is therefore also contingent on human interpretation. The instability of serendipity as a concept is a

reflection of two things: its enmeshed and entangled nature and the methodology which means it is only seen retrospectively.

Serendipity as a Process

Van Andel (1994) emphasizes this temporal nature of serendipity suggesting that Columbus's discovery of the New World was only considered serendipitous when it was realized that he had not landed in India. This illustrates an additional complexity from which serendipity suffers: It needs to be recognized as serendipitous to "count" even when exactly the same actions and discoveries might not be considered serendipitous by another. This recognition has to come after the event because it is impossible for it to come prior to it. Indeed, it may also change depending on the vantage point in the post event timeline. In this way, it suffers from some of the complexities inherent to creativity where linking creativity with social value accords it an unstable ontology (e.g., Weisberg 2010). It is, therefore, not clear whether serendipity can exist outside of people's understanding of it. And it is, therefore, doubly dependent on people – both at time of the event and in making sense of the event afterward.

Lawley and Tompkins' (2008) model (Fig. 1) focuses on this temporal aspect of serendipity and explicitly refers to a serendipitous process rather than a single moment. They make a distinction between synchronicity, where two events happen simultaneously, and serendipity, which may arise from synchronicity or from ordinary events. Within their model all six stages have to occur for an event to be considered serendipitous, and serendipity therefore only occurs post hoc, in the state when it is evaluated by the person experiencing serendipity.

As is clear here, the model refers to a process that wraps around an event. Most of the model is concerned with what happens after the event, and thus the focus is on the role of the person in creating serendipity. The model starts with a "prepared mind" (E-1). Then the event (E) occurs. For E to be considered serendipitous, it must also be recognized as potentially useful, exploited, and

Serendipity, Fig. 1 “Stages of serendipity” taken from Lawley and Tompkins (2008). (Permission granted by the authors)

then evaluated. However, as Makri and Blandford (2012a) argue, while the focus on the process in this model is important, the actual character of that “unplanned and unexpected event” is left rather unclear. As is common in earlier explorations of serendipity, the focus here is on the person in the model rather than the event itself.

McCay-Peet and Toms’ (2015) process model (Fig. 2) has more room for the environment as a trigger for serendipity as part of an overall process. Their model posits an instant phenomenological aspect of serendipity (which parallels the more widely investigated “aha” experience in insight problem-solving, see Danek et al. 2014). However, within an organization for a moment to be serendipitous, it must often be followed up and worked on with varying levels of granularity. This capturing of the moment of serendipity and cementing it is often absent from other models. It is only then that serendipity occurs: both the practical outcome and the feeling that accompanies it are required. Indeed, this model emphasizes the perception of serendipity. It is not enough for all the aspects to come together; there has to be a “feeling” of serendipity to accompany it for the process to be cast as serendipitous.

So we see that serendipity is theorized as emerging from an interaction between a person or people and the environment in which they are located and situated in a timescale. Again, in this model, serendipity only happens when it is recognized as such by the people making the discovery. Without this awareness of serendipity, an event is not categorized as such.

For an event to be serendipitous, the past is important because of both the nature of the narrative framing and the way the mind of the person experiencing serendipity has been “prepared” (Yaqub 2018). Furthermore, because serendipity is often characterized in hindsight, as the end point of a process, the evaluation of the product in that moment is also important. Finally, the future is also key to the recognition of a moment as serendipitous – the evaluation of the happy accident necessarily requires a projection into the future (Copeland 2017).

Just as serendipity is integral to an understanding of what is possible, so the possible is integral to understanding serendipity. The fortuitous aspect of the phenomenon means that it is only serendipitous in relation to the other possibles. The human judgement of the moment can only happen against a backdrop of awareness of other possible outcomes. Serendipity becomes a way of characterizing the path taken which allows for unplanned and unexpected events to play a role in both the possible and the actual.

Individual Differences

Despite evidence that there is a weak link between individual differences and serendipity (McCay-Peet et al. 2015), as discussed above, the majority of serendipity research considers people’s role at the center of serendipitous encounters. This is not unreasonable: it is the addition of sagacity which raises serendipity from accident or random chance

Serendipity, Fig. 2 “The process of a serendipitous experience” taken from McCay-Peet and Toms (2015). (Permission granted by the authors)

and, traditionally, this has been the focus of much theorizing. For many writers it is these internal characteristics that provide the element of control of serendipity (Foster and Ford 2003), and, in wider folk psychology, there are personal characteristics that have commonly been associated with “making your own luck.” Indeed, de Rond (2014) suggests that the only proper analysis of serendipity is the focus on human agency. He suggests that we should conceive of it as a capability, that of being able to match two disparate events.

Makri and Blandford’s (2012a) model, drawn from several interviews with academic researchers, leans heavily on how a person responds to “bisociation” – that is, a new mental connection – which, in their model, can come from the environment or also from a memory. Thus, for Makri and Blandford, serendipity can arise completely internally, and there is a new focus on internal processes. This is also similar to the second half of McClay-Peet and Toms’ model which refers to the process of creating a link between the trigger and either (a) a previously conceived problem or (b) a new, unthought of idea which occurs internally. However, this may not only be difficult to identify but also widens the

definition beyond the core relational aspect which has defined it thus far.

There have been many attempts to define the internal characteristics that make someone more likely to take advantage of a serendipitous moment. Race and Makri (2016) identify four traits: being curious, observant, alert, and assiduous. Rubin et al. (2011) describe two personality traits emphasized in the literature that allow someone to experience more serendipity: noticing and preparedness. All these characteristics describe a person who is highly attuned to the surrounding environment centering that relationship. Indeed, Rubin et al. suggest that the noticing aspect of the person is equally shared with the environment which will highlight things that should be noticed so it becomes impossible to unpick which is most salient. This bidirectionality is also stressed by Björneborn (2017), who discusses three key serendipity personal factors (curiosity, mobility, and sensitivity), but, crucially, these are contingent on and inseparable from the external serendipity factors. This reflects the relational and contingent nature of the phenomenon. There is a tendency in psychological research to focus on human factors, but, in serendipity research, it is impossible

to separate these from the environmental factors – not only are both of them necessary, but they often interact.

Environmental Factors

Beyond the individual differences that may dictate whether or not a person takes advantage of serendipity, researchers are becoming increasingly interested in the environments which facilitate serendipity. In the information retrieval literature, serendipity is seen as a by-product of browsing, and the direct nature of internet searching reduces the likelihood of coming across something unplanned (Foster and Ford 2003). Especially in the fields of information encountering, much of the current interest in serendipity stems from a concern that the increasing digitization of information will reduce flexibility and with this the chances for serendipity. However, this is also an area under much debate with others claiming that the open environment of the internet facilitates accidental discovery by allowing more and a wider range of connections (see Race and Makri 2016 for a summary of the debate occasioned by Gup's 1997 essay "The End of Serendipity").

In a complementary paper to their model cited above, McCay-Peet et al. (2015) go into more detail about the aspects of the environments necessary for serendipity. They are particularly interested in the types of trigger in an environment which can precipitate serendipity in information acquisition. Three forms of trigger were extracted from interviews with researchers: (a) verbal, (b) textual, and (c) visual. The verbal trigger was the most often described, which reminds us that external triggers can be people as well as things – indeed, the authors found the social aspect of serendipity to be readily apparent. The trigger does not need to be immediate (although it can be), and there can often be an incubation delay. The facilitating factors they identify, those within the external environment, all relate to this first stage: an environment must be trigger-rich, highlight the triggers, facilitate recording of the triggers, and encourage the making of connections.

Perhaps the closest examination of serendipitous environments comes from Björneborn (2017, p. 3) who sees serendipity as an affordance or "usage potential." He identifies three key affordances for serendipity that encompass ten sub-affordances. Although he also identifies personal factors, he is unusual in skimming over these and devoting the majority of his framework to the affordances of diversifiability, traversability, and sensoriability. These all refer to the possibilities engendered by an environment.

Diversifiability refers to the diversity of content in an environment and covers the sub-affordances of diversity, cross-contacts, and incompleteness. An environment high in diversifiability facilitates serendipity because it allows for more accidental bisociations and juxtapositions. The clustering of possibilities in an environment increases the likelihood of one of those possibilities being actualized. Traversability refers to the potential affordances to move and access the diverse content. This covers the four sub-affordances of accessibility, multi-reachability, explorability, and slowability. These are four ways of making use of the topology of a given environment. This emphasizes the relational nature of serendipity: An affordance is only an affordance when it is used. Finally, sensoriability describes the way an environment appeals to all the senses and deals with how the environment can make different resources stand out for different senses. It covers the three sub-affordances of exposure, contrasts, and pointers.

A detailed examination of the environments that facilitate serendipity is possible alongside an understanding that, while personal characteristics and environmental characteristics may be necessary for serendipity, they are often not sufficient. These serendipitous environments can arise naturally or can be reinforced deliberately by design. Although there appears to be a paradox in planning for serendipity because serendipity arises from the unplanned, environments can be designed to create more opportunities for accidents to arise (Race and Makri 2016). The designers can plan for serendipity, but it is the users who must uncover things in an unplanned manner (Björneborn 2017).

Methodological Considerations

As we have seen, work on serendipity proceeds from mainly a posteriori position. Serendipity is identified after it has occurred, sometimes even after a significant amount of time has elapsed (Foster and Ellis 2014). The models arise from two different angles: either semi-structured interviews (Erdelez et al. 2016; Makri and Blandford 2012b; McCay-Peet and Toms 2015) or collections of reports of serendipity whether first or third person (Van Andel 1994; Yaqub 2018). There are no models currently that draw their evidence from experimental designs. For example, Yaqub (2018) compiled his taxonomy when given access to Merton's records of serendipitous events that had been sent to him over the course of his life. Van Andel's (1994, p. 631) "serendipity patterns" are based on an overview of his "collection of serendipities," and McCay-Peet and Toms' (2015) model is based on interviews with 12 Canadian academics and professional researchers.

Methodology and construct conception often form a bidirectional relationship: the operationalization of a concept informs the methodology used, but the reverse can also be true. The methodology used to elucidate a concept will inform our understanding of the ontology of that concept. The dominant methodology that has informed research on serendipity has also informed its emphasis. Serendipity is filtered through a lens of human agency because it is researched by asking people how they experience it. Yet, the theoretical basis of serendipity paints it as a relational concept, and, as such, both the external triggers and internal dispositions are necessary.

Serendipity is often conceived of as a process, and, indeed, many of the models that exist are process models. Again, models structure our thinking about a concept, often turning messy heteroscalar processes into linear, perhaps iterative, processes with an implied start and end point. The models reviewed here all suggest that serendipity only exists once it is conceived as such, and so they tend to focus on human agency. The process of serendipity is such that it can only occur when human agency is invoked, and, further, it is often proposed that it is necessary for a

human to categorize the moment as serendipitous. There is an ever-present tug toward a human-centric model of action, even in a concept such as this one which is, by its very nature, enmeshed and entangled. What is possible in serendipity studies is constrained by the way it is approached.

Conclusions

Serendipity is a relational concept emerging from the interactions of people and possibilities. It has a transactional logic – luck arises in the environment but becomes serendipity when it is realized by a person. Serendipity is perhaps best conceived as enacted luck. While it is unhelpful to consider the possible and the actual as diametrically opposed or in a linear temporal progression (possible leading inexorably to actual), an understanding of *how* the possible becomes actualized would be incomplete without serendipity; serendipity is the bridge between the two. Furthermore, serendipity can only be understood as existing in relation to other possible pathways, and so an understanding of the possible is also integral to our understanding of serendipity. We cannot categorize something as serendipitous without understanding how it has broadened our understanding of the possible and also how it stands in opposition to the other possibles. In the end, serendipity interacts with the possible to help us understand how we make sense of a messy world.

Silence

Olga V. Lehmann

NIEFT – The Norwegian Institute for Emotion Focused Therapy / NTNU – Norwegian University of Science and Technology, Bergen, Norway

Abstract

The definition of silence is as vast as the definition of language, movement, noise, or sound themselves. It is so because rather than in opposition or mere contradiction to language, movement, noise, or sound (Kurzon, Discourse of silence. Amsterdam, John Benjamins: 1998), silence is that which blossoms in between them, in interdependence with them (Lehmann, The cultural psychology of silence. Treasuring the poetics of affect at the core of human existence (Unpublished doctoral dissertation). NTNU Norwegian University of Science and Technology, Trondheim, Norway: 2018a). Hence, silence is not to be understood as a pure emptiness, a pure absence, a pure pause: silence is rather a room for the possible. In between one musical note and another, in between words, in between body signals, in between our actions, in between the unexpected noises from the environment, there is a space and a time for being and becoming. Acting at times as a boundary that precedes the unfolding of the future, and at times as a

room for reminiscence or to deepen our present experiences, and some other times as the reminder of the uncertainty that belongs to our human condition, silence is always redirecting us somewhere; it enhances attention inward and outward.

Silence · Silences · Silencing · Stillness · Multivoicedness · Meditation · Self-exploration · Contemplation · Presence Poetry

The Polysemy of Silence

Awkward silences? Mystic silences? Traumatic silences? Given that the word “silence” can evoke a vast range of human experiences, Bruneau & Ishii (1988) and Orlandi (1995) distinguish between Silence, silences, and silencing. According to them, as well as other further elaborations in psychology (Lehmann, 2016a, 2016b; Lehmann, 2018a), Silence in singular, and often with a capital S to begin with, denotes the ineffable experience described by artists and mystics as borderless emotional intensity of communion either with nature, a masterpiece of art, another being, or a spiritual entity. Silences refer to social interactions and communications, such as cues for taking turns in conversations, as well as the intentional uses of words and silences to avoid other themes of conversation. Silencing denotes dynamics of power such as rhetoric, or oppression, for example. Silence, silences, and silencing are interconnected with one another, and at times, some of them can occur simultaneously (Bruneau & Ishii, 1988).

Silence

Throughout history, Silence has been associated with the pursuit of values such as insight, wisdom, or beauty (Braman, 2007; Jensen, 1973; Sardello, 2006). It is an experience of expansion that often brings into our awareness the feeling of interconnectedness with the world and others. For many, these experiences transcend a mere psychological phenomenon and are better explained in terms of spirituality. The tonality of experiences that

Silence entails is available to us as human beings, often, but not all of us reach a language that is evocative enough of its intensity. Poets devote themselves to grasp this intensity more fully, and at times, one of the purposes of poetry is to evoke that which is ineffable (Paz, 1956/1999). Some of the realms of Silence have also been explored in different notions such as poetic instants (Bachelard, 1932/2013; Paz, 1956/1999), mystical experiences (James, 1901, in Schneider & Berke, 2008), or oceanic feelings (Ramakrishna and Freud in Harrison, 1989), just to name a few. One example of these aesthetic, contemplative, and meditative practices is *Chado* – The way of tea, the traditional Japanese tea ceremony (Murakami, 2017). As the example of the tea ceremony acknowledges, the aesthetic quality of embracing silence through standardized rituals fosters awareness of, and raises attention to, aspects of life that could otherwise be ignored.

Silences

In the context of our social interactions, for communication to be effective and assertive we need words and body language, but we also need of silences to give room for understanding, empathy, and reflection. We use spaces in between words and actions for different purposes, and those intentions can backfire at us if we do not bring enough awareness to the needs and wants beneath our uses of words and silences. Silences then refer to the space and time we take to process information, take turns, reflect, and deal with the hesitations that emerge as we are communicating with others (Bruneau, 1973; Mazzei, 2007).

There are diverse forms of silences, such as textual, situational, thematic, and conversational (Kurzon, 1998, 2007, 2009, 2013). Textual silences involve an intention to be concentrated or focused on a specific task, such as reading, by being silent (Kurzon, 2009). Situational silences are mainly group experiences that regard more ambiguous social cues, as there is an intention to be silent to promote a value, such as minutes of silence in memorials (Kurzon, 2009, 2013). Thematic silences refer rather to the uses of some topics of conversation to avoid speaking of others,

which remain then silent (Kurzon, 2009). Conversational silences take place when for one or other reasons one of the persons involved in a conversation does not respond or does not actively participate with words or actions (Kurzon, 2009). For example, in the context of psychotherapy these silences are assessed as either obstructive, neutral, or productive (Levitt, 2001a). While neutral silences indicate the client is using this space in between words to make associations or connect with different memories, obstructive silences show disengagement or repression (Levitt, 2001a; Stringer et al., 2010; Stone et al., 2012). Productive silences have different functions in the context of therapy, such as them being a sign of interpersonal connection, insight, and emotional expression (Levitt, 2001a). It is important not to underestimate those silences are dynamic and even obstructive silences can become productive silences may they be addressed in ways that enhance relational depth between the client and the therapist (Levitt, 2001b; Cooper, 2013). In other words, silences, being rooms for the possible, do not have a permanent meaning or emotional intensity.

Silencing

Silencing denotes authority and forms to impose power and control during social interactions (Bruneau, 1973). Even if the temporary dominance from one or the other parts in social interactions can convey a sense of order and direction, excessive or one-directed dominance brings unbalance and obstructs dialogue (Hermans & Gieser, 2011). For example, in the theory of the spiral of silence is argued that people who see themselves as part of a minority group would, often, conceal their perspectives due to their fear for being further isolated or oppressed (Noelle-Neuman, 2008). However, more theoretical and empirical attention is needed to better understand the complexity of emotional processes that lead to silencing (Lehmann, 2018a; Moy et al., 2001; Noelle-Neumann, 2008). Research on trauma and abuse sheds light to this issue. The need to be protected from discrimination, violence, abuse, or rejection can lead to conscious and unconscious silences, which can be dilemmatic because among

other things, these silences could be misunderstood as consent (Kurzon, 1998; Mazzei, 2007; McIntyre, 2013; Stone et al., 2012). At times, after having been victims of abuse, violence, discrimination, or rejection, people keep using silences as a form for self-preservation or as an attempt to overcome the traumatic experiences they have been through (Sorsoli, 2010). In other contexts, the perpetuation of silences has to do with people perceiving that they are in a lesser position in a hierarchy or that they have less authority than the other part, anticipating that their voice would not be heard or that they would affect the relational dynamic (Bruneau, 1973). An example of this is the relationship between doctors and patients, where patients more often than note fear to communicate to their doctors when they perceive that they are making mistakes (Schwappach, 2008). In other contexts, there are ideologies and sociocultural structures that make some topics become taboos, and people internalize authoritarian voices being less prone to speak of topics such as sexuality, race, politics, and so on (Freud, 1913/1999).

The “Polyphony” of Silence

In musical scores, silences have their own notation system and play a crucial role in the rhythm and melody of compositions. As in music, silences make part of the rhythm and melody of our everyday lives. Imagine silence being a room, a space where our attention is redirected inward and outward. Then, the explicit focus on what Silence, silences, and silencing entail can help cultural-developmental psychologists to explore attention as a higher psychological function, complementing previous theoretical advances in the study of memory, imagination, and creativity (e.g., Murakami, 2017; Wagoner, 2017; Zittoun & Glaveanu, 2016), just to mention some.

One important feature of attention, which silence sheds light into, is that we are constantly relating to simultaneous stimuli, some of them distracting us, or some others into the focus of our awareness. In the mind, these simultaneous stimuli could be, for example, feelings and emotions, thoughts, and images, which relate to

different external persons or versions of ourselves. Following the premises of dialogical self-theory further, one can consider the mind as a theater with different I-positions which can be external (a mother, a partner, a teacher) or internal (I-as-daughter, I-as-girlfriend, I-as-teacher). At times, the musical notion of polyphony is often used as a metaphor of the multivoicedness of the self (Hermans et al., 1992; Yamada, 2008). However, what is seldom acknowledged is that in musical theories polyphony refers to just one of the forms of the simultaneity of tones, voices musical instruments, and silences. That is, polyphony implies that these simultaneous stimuli or positionings of the self have different directions (Bakhtin, 1963/1999; Klempe, in press-b; Lehmann, 2018a, 2018b), whereas when the stimuli in a musical piece have a similar direction, it is known as homophony (Bakhtin, 1963/1999). Having made this precision, what exploring silence in everyday life can offer for psychology are the ocean of possibilities to explore these tensions that are formed between diverse positionings of the self as we relate to the environment and the inner activity of the mind.

Having acknowledged that silence is not a pure phenomenon, to study it we need to focus on its unfolding within the simultaneous coexistence of other phenomena. A general framework to do so is to explore silence in the crossroads with language, movements, noises, and sounds (Kurzon, 1998). While writing this article, I can hear the noises of the ventilation. The noise provoked by the movement of my fingers hitting the keyboard distracts me from time to time. I miss the sounds of the piano playlist I oftentimes use to accompany my writing sessions. I am not talking out loud, but the inner conversation I keep with myself as I write is accompanying this silent morning in Bergen. In addition, there is a melancholic emotional tune which coexists with me-as-writer: there is a grief and the wish to resolve a conflict with someone I deeply care about, and the constant idea that I cannot do much more than being silent and letting time heal what my words have implied. In this order of ideas, when we explore silence from the perspectives of multivoicedness and simultaneously, we can gain a deeper understanding of its

functions. For instance, silence can contribute to either bonding or separation, healing and wounding, exposure or concealing, assent and dissent, thoughtfulness, and emptiness (Jensen, 1973; Lehmann, 2018a). May we study higher psychological functions from a linear perspective, we could focus on one positioning of the self (e.g., I-as writer sitting in “silence” as I write), whereas what is actually occurring within a person who sits and does not talk is way more diverse and complex than that. More research is then needed following dialogical approaches in psychology, which give account of what are the processes that the multivoicedness of the self undergoes before, during, or after periods of inner silence (Lehmann et al., 2018).

Studying Silence

Perhaps one of the most prominent fields of research in relation to silence is that of meditative or contemplative practices, some of which are featured as mindfulness studies. There are several kinds of meditation practices, many of them relating to what is brought as the focus of attention (e.g., a mantra, the breath, body awareness) and what is the intention (e.g., relaxation, generating a virtue such as compassion, self-exploration of the contents of the mind) (Holen, 1976/2016; Siff, 2010). Either if approaching meditative practices in a secular or a spiritual way, the silence one searches through them is a path and an opportunity to tune with a sense of wisdom (Kabat-Zinn, 1994). However and again what appears as a misconception is that the silence experienced in meditation is an emptiness. Since the only way to experience a pure emptiness in silence would be to die (Cage, 1961), then to search for silence is to approach and detach from the contents of the mind. Such a movement of immersion in the felt intensities of an experience, as well as detachment, observation and reflection upon an experience opens a room for the ocean of possibilities for us to align our intentions, attitudes, and actions as we adapt to different circumstances. Therefore, silence is about being present with what is; it is a practice of noticing and intuition of the moment.

Once we master this craft, silence can convey us with the agility to balance the doing and the not doing, an agility and intelligence to adapt to life's circumstances and mysteries. In doing so, silence is a tool for us to bring the possible into real in terms of conscious choices that affect our creativity and relational depth, for instance.

Rather than encouraging people to avoid or feel ashamed for whatever is brought into awareness when we are sitting in silence, meditators could therefore be encouraged to accept and notice what are the feelings, thoughts, images, and fantasies that arise (Moniz & Slutzky, 2016; Siff, 2010). Meditating could be also then understood as a process of reconciling ourselves with the fact that we are our minds, and the observers of our minds, and that meditating is a path to investigate our minds (Thich Nhat Hanh, 1975/1995; Kirmayer, 2015). Therefore, it is not strange that the notion of silence is at times used as a metaphor of listening (Wideman, 2001). This is not as far as we might initially think, from notions that have been important in the history of psychology such as apperception, self-observation, inner perception, introspection, or insight. Either it being a laboratory or a religious setting, pursuing the knowledge about the mind has been revolving around using language to describe and express what appears in the stream of consciousness (Wagoner, 2013). For instance, Wilhelm Wundt used to train his study participants to report the contents of their perceptions, such as sharing out loud what was appearing in their stream of consciousness (Cattel, 1928). He defended the advantages of requesting immediate reports to avoid distortions in memory (Wagoner, 2013; Benetka & Joerchel, 2016). Later, the Würzburg School, following some of the premises of Wundt, used other methods for immediate reconstruction of mental activity as the study of self-observation (Humphrey, 1951; Hoffmann & Stock, n.d.; Benetka & Joerchel, 2016).

In addition to oral reports, journaling accounts have also been at the core of the registering and study of self-exploration processes (Allport & The Social Science Research Council, 1942; Siff, 2010; Lehmann, 2018a, 2018b). However, self-exploration is not just a matter of language, it is a

matter of uses and functions of silence as well. At times, silences give room for the associations between human experience and language to take place. In other occasions, the felt intensities of human experience transcend the capacity of language to fully express them. When looking across history of religion and philosophy, but also into the history of psychology itself, there are two features that are used to describe wisdom, values, and insight: silence and poetry. From Plato to Whitman and many more, there are several poetic descriptions about the value of silence for human beings (Corbin, 2018). Poetry, being the most musical nuance of language, is also the realm of language which is the closest to the depth of our emotional world, which is the closest to the ineffable, and which gives enough room not just for words, but also for what words cannot say. That is, the study of silence is interdependent of oral and written language that can describe what silence evokes, and other creative methods that include artistic expressions can also shed light to the emotional intensities that words often cannot (Lehmann, 2018a; Lehmann & Brinkmann, 2019).

Cultivating Silence, Silences, and Silencing

There are several forms to cultivate silence in our everyday lives. Following the premises that training mindfulness is to train our attention, our intentions, and our attitudes (Shapiro et al., 2006), we could argue that cultivating silence requires from us to clarify an intention for what we want to experience as silence, an attentional focus to what is considered silence and a distraction from it, as well as attitudes such as curiosity, gratitude, and patience, so as to let silence be our teacher. In general, we can say that we can cultivate silence in at least three ways: by means of listening, by means of saying, and by means of encountering, all of which can facilitate relational depth (Lehmann, 2016a, 2016b, 2018a).

In a nutshell, we can practice listening when we want to attend to what another is saying, by means of noticing distractors and bringing

awareness back to the words of the other. However, we can also practice by aiming at staying present when we do not want to listen to another person, but we know listening might be important. Similarly, we can practice silence when saying something by intentionally regulating the rhythm and contents of our words, and what which we chose not to say might be as important as what we say. Self-exploration via meditation, journaling, or therapy could help those who want to cultivate silence to become familiar with their attachment styles, personality traits, and sociocultural frameworks. This expanded understanding of the self can support them to better navigate the uncertainty that silence brings forward. For example, people who have avoidant attachment styles, introverted tendencies, and belong to individualistic cultures might crave, even if at times unconsciously, more solo space in interactions and appear as quieter in communication (Cain, 2013; Johnson, 2008; Triandis and Gelfand, 1998). What psychotherapy research has widely explored is that for silences and silencing to facilitate human connection and relational depth, they need a frame. Silence is a container of experience, a room for possibilities, and for these possibilities to be as aligned as possible with our desires and goals, some explicit lines are needed. In other words, from a perspective of clinical psychology we could argue that there are healthier ways for the possible to unfold than others. Silence facilitates a healthy unfolding of the possible when promoting insight, as well as an expansive, flexible, and dynamic understanding of the self, the world, and other beings. This expanded comprehension of reality can facilitate a sense of interconnectedness, dialogue, and virtuous actions. For example, when taking a time of in a heated argument it is important to acknowledge that the emotional overwhelm is too high to pursue communication, express the need for silence, and suggest a time when both parts are to return to the argument, and then proceed to activities that are soothing during the silent period (Gottman & De Clair, 2001). Given we might fail in recognizing our need for silence or our need to break silences in the context of social interactions, the craft of silence is also a craft of humility, patience, and

repair. Often it would be important to speak about the impact that silence is having in our emotional world, to reduce the uncertainty and expand our tolerance window to it.

When it comes to the realm of Silence, these are often experiences that are so emotionally intense that we can feel in communion with a piece of art, with nature, with another being, with ourselves, or with a spiritual entity. Either in secular or religious forms, Silence can lead to an experience of freedom and eudemonic happiness, given that the insights and wisdom gained during silence can help people better connect to human virtues (Lehmann et al., 2018). Several rituals across cultures serve the purpose of expanding our receptivity for such encounters. Just to give some examples of it, such as visiting religious temples or solo experiences in nature (Kagge, 2018; Lehmann, 2018b; Tangene, 2017), prayer (Sarah & Diat, 2017), aesthetics and art (Lehmann, 2018a, 2018b), spending quality time with others, attending to silent retreats of different forms, or being parts of cultural practices, such as the Japanese way of tea (Murakami, 2017). In line with these, there is already evidence from mindfulness research supporting the fact that embracing Silence expands the awareness and appreciation of beauty (Shapiro & Carlson, 2017). An important aspect of silence being a practice is that we also need to adapt to the tools that facilitate its experience. For instance, if thriving in the silence of nature, one needs to also have the skills for sailing a boat, hiking, climbing, or surviving in rough weather conditions (Kagge, 2018; Tangene, 2017). Or, knowing some techniques of how to master journaling in the alternation of sitting or walking practices of meditation, contemplation, or aesthetics, given that writing about such experiences can foster insight (Siff, 2010; Lehmann, 2018a).

This being said, the path of cultivating Silence, silences, and silencing in nourishing way requires from us to embrace our human condition and our existential givens. What happens when it comes to cultivating silence is that we human beings tend to idealize such experiences and assume that we need to flow into silence and spontaneously land into the intuition of what to say, how to say it, how

to listen, or how to be in communion. However, the intention to aspire for Silence, rather than the unrealistic expectation of perfecting it, is what can render it possible to keep self-exploration and relational depth as goals, while learning on the way what are the belief patterns, emotional injuries, and (or) traumas that separate us from achieving them. Several mystics have acknowledged that noticing fears, inner conflicts, and the diverse tensions that form mental activity are part of aspiring for silence and not necessarily a disruption of silence itself (Thich Nhat Hanh, 1975/1995; Saint Teresa of Jesus, 1577/2015; Merton, 1968/2000). The avoidance of the inner conflicts that silence sheds light into during meditative practices, for example, has been linked with diverse side effects such as regression to childhood traumas, arousal of narcissistic tendencies, and other psychological problems (Epstein & Lieff, 1981; Epstein, 1990).

Conclusion: Silence and the Possible

In our everyday lives, silence is a room for the possible. Either it is the possible understood as an outcome, as the way in which the future unfolds according or not to our expectations, a possible meaning to an experience, the deeper intensity of the present moment, or the awareness of the uncertainty that belongs to our human condition – silence is a container for us to feel into, as well as to better comprehend our experiences and our existence. When a person suddenly stops speaking, or a musician prolongates the space in between sounds, we wonder: What is next? Awkward silences in social interactions also evoke the challenges of making sense of the uncertainty that silence gives room for. However, uncertainty is a part of human existence, and silence just amplifies our awareness of uncertainty given the contrast that it represents in the flow of activities (Lehmann, 2018a). To cope with uncertainty, either consciously or not, the mind redirects attention inward or outward, and hence, studying silence is in one way or the other the study of attentional processes. Therefore, cultivating silence is a path for self-exploration and the

embrace of the human condition, befriending qualities such as culture, attachment, and personality, awareness of which can facilitate the alignment of practicing silence with clear intentions, attitudes, and focus of attention. Here, it is a room for psychology for further development and studies of higher psychological functions and consciousness. However, the dilemma this represents for psychology is that Silence is at times described as a psychological phenomenon and as a spiritual one. Given that in psychology the distinction between the mental and the spiritual has been dilemmatic and at times problematic, the ontological dilemma between the mental and the spiritual is therefore still to be further addressed in contemporary psychology.

Simulation

Henry Brighton and Wendy Powell
Department of Cognitive Science and Artificial Intelligence, Tilburg University, Tilburg, The Netherlands

Abstract

A simulation is an orchestrated series of operations used to model the behavior of a system. The system being simulated could exist, such as the world economy, have existed, such as a transition in evolutionary history, or be hypothetical, such as the synthetic world of a computer game. A simulation will typically model how a system develops over time, and potentially at a fidelity that is hard or impossible to

achieve using other kinds of model. Most simulations are specified formally, either mathematically or algorithmically, and executed on digital computers. As a tool for modelling and understanding the natural world, simulation is used throughout the sciences to model systems ranging from the global climate, financial markets, immune systems, power plants, and the origins of language. Simulation is possible and is the primary method of inquiry for fields, such as artificial intelligence and complexity science. More broadly, simulation is used to engineer virtual environments for training and entertainment, create artifacts, and explore design spaces. High fidelity simulations that operate in real time can blur the distinction between virtual and natural worlds. In each of these applications, simulation provides a way to create, analyze, manipulate, and crucially automate models with the possibility of an arguably unparalleled flexibility and scope.

Simulation · Computer simulation · Virtual reality · Artificial intelligence · Artificial life · Complexity science

Introduction and History

Simulation techniques developed and flourished in parallel with the emergence of programmable computers during the 1940s. Attempts to develop automated, mechanistic models of natural and hypothetical systems, though, predate programmable computers and underscore several subtleties that make defining the concept of simulation problematic. For example, during the industrial revolution in the late 1700s, the term *computer* referred to a person employed to carry out the laborious arithmetic calculations needed to approximate various mathematical functions (Daston 1994). These calculations required following an iterative procedure known as Newton's method. With the goal of replacing these computers with a machine, Charles Babbage devised the difference engine in 1822. Babbage's

machine, when viewed as a means to model the activity of the people carrying out the calculations, simulated the work of the human computers. But when viewed as a means to implement Newton's method, however, Babbage's machine is more an example of automation rather than simulation. In the same way, a pocket calculator automates the operations of arithmetic rather than simulates them. Although such subtleties can make defining the concept of simulation problematic, most accept that the key characteristic of a simulation is that it models how one system develops over time by automating a different but related system that develops over time (Hartmann 1996).

Modern use of the term simulation almost exclusively refers to computer simulation. Indeed, the advent of fully functional stored program computing devices during the latter part of the Second World War spurred the development of the simulation techniques used today. During this period, Alan Turing laid the foundations for the theory of computation by formulating what are now termed Turing machines, notional computing devices that he imagined carrying out operations on a tape, much like a simulation of humans working with paper and pen (Turing 1937). Turing, in particular, considered how an appropriately designed machine could take as input the description of an arbitrary Turing machine and then simulate it. He also speculated how his machines could simulate other kinds of systems such as the nervous system (Turing 1948). Turing machines, conventional computers, and neural networks are models of universal computation, which means that they are formally equivalent to each other in the class of functions they can compute. Computer simulations are therefore restricted to modelling systems whose dynamics are tractably computable, which includes a huge diversity of systems which may otherwise appear unrelated to familiar computing paradigms and tasks. Turing didn't use the term simulation. Less than a decade later, though, a generation of theorists inspired by his work adopted the term when proposing a new field of research, artificial intelligence, which set out to examine the conjecture that any aspect of human intelligence could

be simulated by a computer (McCarthy et al. 1955/2006).

Mirroring the steady adoption of computers as tools for scientific research from the 1950s onwards, simulation has become commonplace in practically all areas of science, and more recently, in areas of inquiry preoccupied with innovation and the creative process, such as design and the visual arts (see ► [“Possible of Design”](#)). These varied uses of simulation can follow different methodologies and work toward different goals. In virtual reality and computer games, the ability to create and control high fidelity, high resolution models is often a key objective (see ► [“Virtual Reality”](#)). In contrast, when used as a tool for scientific inquiry, the goal of simulation is rarely to model a system as accurately as possible but to instead isolate a minimal set of assumptions needed to generate and explain some phenomena of interest. In each of these applications, simulation modelling makes possible the automation and control of potentially complex models in ways that are hard or impossible to achieve otherwise. As the following examples illustrate, simulation has become a highly productive means to explore the possible.

Simulating Possible Pasts: The Origins of Language

Simulation is ideally suited to modelling systems composed on many interacting parts that change over time in ways that are hard to predict. An archetypal application is evolutionary computation, a field of research focused on simulating the evolutionary process. Viewed at scale, most agree that life on earth has been punctuated by major evolutionary transitions, each introducing a new mechanism for information transmission across generations with the potential to drive the evolution of systems of greater complexity (Maynard Smith and Szathmáry 1995). For example, the evolution of the genetic code supported the transmission of larger genomes. The evolution of language, which is the most recent major transition, has proven to be particularly difficult to explain. Theories of how and why this complex

and highly structured yet idiosyncratic communication system emerged were banned from publication by the Linguistic Society of Paris by in 1866 due to being speculative and untestable (Stam 1976). The 1990s saw a resurgence in interest in these questions, which ultimately led to the development of evolutionary linguistics as a mature field of research (e.g., Hurford et al. 1998; Briscoe 2002). Simulation was instrumental to this development. It allowed a new generation of theorists to model and explore complex interactions between biological evolution, cultural evolution, and linguistic development within the individual. The ability to systematically study these dynamic systems using simulations lead to new theories, the assumptions and implications of which could be scrutinized in ways not available in the past (see ► [“Emergence”](#)).

Many of the theorists who adopted the methodology of simulation took the opportunity to challenge the traditional view that the characteristic structure of language is an expression of the genes (Chomsky 1965). One alternative theory rested on the conjecture that the structure of language is in large part an outcome of the process of repeated cultural transmission from one generation to the next (Kirby and Hurford 1997; Briscoe 2002). On this view, certain regularities in language evolve and persist due to being robust to repeated cultural transmission (Brighton et al. 2005). Initially, this conjecture was speculative, controversial, and in need of formal specification. Simulation allowed rapid prototyping of formal models providing proof of concept, followed by the systematic study of a wide range of initial conditions and assumptions that established the boundary conditions for the cumulative evolution of linguistic structure. Rather than develop increasingly complex, high fidelity models, the focus then turned to identifying the minimal set of assumptions, and the simplest models capable of explaining the evolution of linguistic complexity. In short, from the bewildering complexity of the many interacting processes that led to the evolution of language, the methodology of simulation not only spawned a revived interest in this previously speculative area of inquiry, it generated new and testable theories of how this major

transition in evolution occurred. The stages of theory development outlined above also underscore the more general point that simulation is often critical to the discovery of new theories, even if they are subsequently communicated and justified using conventional mathematical models.

Simulating Possible Futures: Artificial Intelligence

Building on a long history of attempts to engineer mechanistic versions of living organisms, the field of Artificial Intelligence (AI) emerged in the 1950s from the conjecture “that every aspect of learning or any other feature of intelligence can in principle be so precisely described that a machine can be made to simulate it” (McCarthy et al. 1955/2006, p. 12). Referring explicitly to simulation in its founding definition, AI seeks to extend the horizon of the possible by not only constructing machines that simulate biological systems like humans, but also new forms of intelligence that don’t exist in nature. For example, chess-playing machines, robotic vacuum cleaners, and self-driving cars. These ambitions force us to confront fundamental questions about the nature of simulation. For example, when does a simulation cease to be simulation but instead an autonomous device to which, potentially, we attribute moral status? More specifically, use of the term simulation in AI typically refers to software agents as opposed to physically instantiated autonomous systems. Most autonomous robots, for instance, are not referred to as simulations. On the other hand, a robot with a navigation system inspired by a desert ant could very well be seen as a simulation of the ant’s navigation system, despite being a physically instantiated autonomous device (Lambrinos et al. 2000). In other words, the *use* of one system to model another system is the defining characteristic of a simulation rather than the particular properties of the substrate used for automation.

Another question raised by AI is the phenomenological status of simulations. Most notably, John Searle (1980) coined the term “strong-AI”

to characterize the assumption that creating a thinking machine is a matter of devising the right program, or equivalently, the right simulation. According to Searle, advocates of strong-AI believe that thought, intentionality, and consciousness are properties of a system that emerge from the algorithm being executed, and independently from the physical nature of the device executing the algorithm. Put simply, a simulation of a mind *is* a mind, and the study of thinking machines can proceed without concern for the physical characteristics of the machinery. Searle proposed a refutation of this proposition with a thought experiment. He imagined himself in a room where he manipulated meaningless symbols according to a set of rules. To the outside world, however, these symbols are Chinese characters, and Searle is answering questions written in Chinese. Searle argued that his responses, like a computer’s responses, could be behaviorally identical to native Chinese speaker yet he, like a computer, would not understand a word of Chinese. Programs manipulate symbols whereas minds attach meaning to them, so thinking machines are more than just programs, and more than just simulations. Searle’s critique of strong-AI was met with a series of counterarguments, many of which he rebutted, but some are still being debated (Cole 2019).

Simulating Possible Presents: The Growth of Social Networks

As well as exploring the unobservable past and potential futures, simulation is equally well suited to understanding the observable present. A familiar feature of the modern world, especially since the advent of World Wide Web, is the role of social networks in influencing human behavior. For example, many people are familiar with the idea that everyone on earth is only six or fewer degrees of separation from the US President. This is one implication of the small world hypothesis explored by the sociologist Stanley Milgram (1967). Milgram was interested in how human social networks tend to be structured as small worlds, in the sense that any two people, however

socially, economically, or geographically distant, are connected by a surprisingly short chain of acquaintances. This is an empirical claim that can be tested, but why might we expect this phenomenon, and how might it be explained?

The work of Watts and Strogatz (1998) helped to resolve these questions by using simulations to model the growth of social networks. Reflecting on this work, Watts (2004) recapitulates in detail how simulation “enabled mathematicians to become experimentalists, testing their theories in a multitude of imaginary laboratories where the rules of reality can be adjusted at will” (p. 77). In particular, through a series of simulations, Watts and Strogatz iteratively simplified their models by investigating how various single parameter models could generate small world networks. For example, their alpha parameter model generated networks by regulating the probability that two people with a mutual friend will become connected in the future. Some regions of this parameter space generated small world networks, while others didn’t. The work of Watts and Strogatz, like the research into language evolution discussed above, neatly illustrates how the methodology of simulation in the sciences has a strong tendency to take phenomena associated with highly complex systems and attempt to recreate the gross properties of these phenomena with the simplest models possible (see ► “Complexity” and ► “Emergence”). As the following examples show, the methodology of simulation can also proceed in the opposite direction.

Simulating Alternative Worlds: Virtual Reality and the Visual Arts

Virtual Reality. A typical simulation will model a system that is distinct from the user and will operate without any human interaction during its execution. The study of Virtual Reality (VR), on the other hand, allows simulations to be experiential, rather than merely observational (see ► “Virtual Reality”). The user interacts with a digital representation of a real or imagined world which can respond to their actions in real-time (see ► “Virtual Reality”). The origins of modern VR

can be found in the work of pioneers such as Morton Heilig (1962) and Ivan Sutherland (1965), culminating in the sophistication and diversity of modern VR systems. These systems immerse the user’s senses in digitally-simulated interactive content via a head-mounted motion-tracked display device. Specifically, VR is a form of simulation where gravity, interactive forces, liquid flow, and even weather systems might be modelled. The use of simulation in VR will tend to value high fidelity visual representations of simulated worlds composed of complex processes, systems, or events, as opposed to the simple, abstract, and transparent representations needed to explain some phenomena of interest, as described in the preceding examples.

Many VR systems are driven by educational goals, and since the 1990s, the idea that first-person experience and nonsymbolic interactions with immersive systems can support the acquisition of knowledge has gained considerable traction (Winn 1993). This experiential and constructivist pedagogical approach to learning drives most educational VR applications (Johnston et al. 2018) (see ► “Possible in Education”). Indeed, VR enables the transformation of abstract ideas into perceptible representations using virtual objects (“reification”) in, say, numerical simulations (Gupta et al. 2019). The visual scalability of virtual objects and environments, to take another example, allows users to explore simulations on a macro and micro scale such as when exploring inside and outside the quantum atom (Kontogeorgiou et al. 2008). In short, the key features of VR, namely, multisensory interaction, invisible interfaces, and technological immersion, contribute to the phenomenon of presence, the psychological sense of “being there” within the digital world, and transforming the users into active participants in the simulation (see ► “Virtual Reality” and ► “Human-Systems Integration”).

The Visual Arts. Just as simulation allows scientists and technologists to create and analyze possible worlds, visual artists have adopted simulation as a means to generate imagery and create digital artifacts (see ► “Imagery” and ► “Illusion in Art”). For example, John Gerard’s *Western Flag* (2017) is a simulation of the now disused

site of the first oil find, in 1901, at Spindletop, Texas. This work generates highly detailed imagery of the original site along with a flagpole emitting simulated pressurized black smoke resembling a flag. The simulation operates in real time, reacts to current weather conditions, and is displayed on giant LED screens. Western Flag has been exhibited in multiple international locations and sizes, and raises issues relating to the invisibility of toxic by-products of the oil industry. In short, Gerard's work underscores how simulation can be used to create real-time and dynamic artifacts, the state of which are regulated by the current physical environment.

Conclusion

All forms of modelling, such as mathematical and statistical models, descriptive models, and physical models, make possible the development and analysis of imagined systems. In what senses are simulations substantially different to these other kinds of model? Simulation affords unique opportunities for discovery when we consider issues of complexity, automation, and computation. Furthermore, simulation raises philosophical issues relating to the difference between simulated and natural systems and the role of humans within these systems.

Simulation and Complexity. Simulation is ideally suited to modelling systems composed of many interacting components that evolve over time in ways that are analytically intractable, or too laborious, to determine by other means (see ► [“Complexity”](#)). The components of a simulated evolutionary system might be genomes in a population, and the components of a simulated immune system might be cells within an organism (Chaudhury et al. 2014; Kitano 2002). Furthermore, the rules determining how these components interact may themselves be complex systems. For example, when modelling language evolution, how the system transitions from one state to the next could be determined by a computational model of language acquisition implemented in thousands of simulated language users (Brighton et al. 2005). Understanding how,

at the scale of a population, such systems evolve over time will often involve modelling many millions of interactions that cannot plausibly be represented or determined with any degree of fidelity using conventional modelling techniques (Bonabeau 2002) (see ► [“Emergence”](#)).

Simulation and Automation. Simulating complex systems requires automation, which almost always refers to the use of computers to represent and calculate how a system evolves from one state to the next. Computers make complex simulations feasible, but also provide an unparalleled freedom to experiment with the initial conditions and the rules that govern the dynamics of a simulation. Many instances of a simulation can be executed concurrently by clusters of high-performance computers, allowing vast spaces of model parameters to be explored with minimal effort. Another advantage of automation is the ability to implement real-time, immersive VR simulations that allow humans to engage with and influence the state of the simulated system. Flight simulators, for instance, model the complex interactions between a simulated aircraft, a simulated environment, and a human actor (see ► [“Virtual Reality”](#), and ► [“Human-Systems Integration”](#)).

Simulation and Computation. What can be simulated using a computer is bounded by what is tractably computable. The nature of the system being simulated, however, may bear little resemblance to the structure and function of digital computers. Analog systems such as the nervous system can be simulated with arbitrarily high precision, as can any physical system traditionally described using the mathematics of continuous functions (Trenholme 1994). Indeed, simulations are often viewed as subcategory of mathematical models. While it is true that any simulation can, ultimately, be specified mathematically, this perspective obscures the fact that simulations can be, and often are, created by modelers who lack the formal knowledge needed to express and analyze models mathematically. Anyone who can design software can design simulations.

Philosophical Issues. When modelling, the aphorism “a map is not the territory” (Korzybski 1958, p. 750) clarifies that the goal of a model is to capture an insightful abstraction rather attempt to

replicate the system being studied. While this goal may drive the practice of modelling in much of scientific inquiry, there is a tendency among some to view simulation as means to replicate systems with high fidelity. Taken to an extreme, some AI researchers are driven by the goal of whole brain emulation, where it becomes possible to replicate a person's mental state in a simulation (Sandberg and Bostrom 2008). This issue is directly related to Searle's Chinese room argument of the preceding discussion, which challenges the idea that mental states are merely computational states. Taken to a further extreme, some researchers have proposed a simulation hypothesis, which conjectures that there is a high probability that we currently exist in simulation (Bostrom 2003) (see ► ["Reality"](#)). However one views such conjectures, they underscore the diversity of goals among those who use simulation, and the technical and philosophical possibilities that simulation has inspired (see ► ["Possible in Philosophy"](#)).

Abstract

Social change describes the transformations of a society in terms of values systems, social organization, and practices. What may appear a radical idea at one moment in history can become a taken-for-granted norm at another. Woman’s suffrage, civil rights, and environmental concern are all powerful twentieth-century examples of this. The same might be said for the normalization of new technologies, such as the Internet, smart phones, and AI. The prototype of dramatic social change is the French revolution, which aimed to create a sharp break with traditional society and socially engineered a new one based on the enlightenment ideals of liberty, equality, and fraternity. Yet its ultimate failure to uphold its values and achieve the strived for society demonstrates some of the inherent limitations to radical social change. Social change often

coincides with, and is driven by the idea of, a possible future society different from the current one – in other words, an awareness of the difference between the actual and the possible opens up. This can happen when we are confronted with other societies’ ways of doing things, a minority that persistently communicates an alternative view of reality, and more specifically social movements’ imaginations of alternative futures and motivation to actualize them. Whether efforts to bring about social change are successful depends on both power and moral vision – if it is effectively communicated and connects up with the public’s values.

Social influence · Protest movements · Cultural contact · Arab Spring · Imagination · Moral psychology

Contact Drives Change

One of the most obvious drivers of social change is the contact of groups, especially those with vastly different ideas, values, practices, and technology. Such contact brings to the fore the *possibility* of other modes of believing and acting, as well as material artifacts and technology. The early twentieth-century school of anthropology called *diffusionism* (which included Rivers, Boas, and Bartlett) emphasized how most social changes were caused by the contact of cultures rather than internal developments within them. Ideas, practices, and technologies tended to be taken over by different groups rather than invented anew (see Wagoner 2017). However, in this process the new tends to be combined with the old, such that it is uniquely placed and adapted in each society. Furthermore, genuinely new ideas and practices can emerge from the synthesis of existing cultural forms (Bartlett 1923). This is also visible in new developments in the arts and sciences within the same society (Bartlett 1958).

As a result of these processes societies that are in regular contact with others tend to change at a faster pace. Icelandic language, for example,

changed little over centuries because of its relative isolation from other societies – its modern form is much closer to Old Norse than other Scandinavian languages. At a macrolevel, Jared Diamond (1997) argues that one of the main reasons Columbus sailed to the Americas, and not the reverse, was that the geography of Eurasia provided regular fluid contact between groups, such that innovations in one could easily spread to others. He focuses principally on the diffusion of domesticated plants and animals, technology, and germs, but the principle could just as easily be applied to ideas (he does consider the invention of writing).

The “Colombian exchange” (of plants, animals, and germs) that followed the “discovery” of the Americas also opened up an imaginary world of possibilities. Stories of strange people that tattooed their face and ate human beings flourished, as did people’s consciousness of belonging to a distinct culture among other possibilities (Anderson 1983). Thus, the very contact with other groups can create *reflection* on a group’s own belief system and practices, and in a sense relativize them (Shweder 2017). This can occur by exposure and appropriation of new ideas or practices that develop or even enhance a group. Or, in contrast, it can also lead to reflection based on conflict with, or resistance to, new ideas and practices (Gillespie 2008). In an increasingly globalized world these processes are accelerating (Geertz 2012).

This perspective can also be applied to the interactions between groups in the same society. Great innovators are often great synthesizers across the knowledge bases of different groups. Furthermore, the relationship between scientific groups and the lay public has been identified by Moscovici (2000) as a particularly fertile site for the construction of new ideas. He analyzes how new scientific and technological discoveries are collectively elaborated by the public, enriching everyday language and feeding imagination of new possibilities. Moscovici’s (1976–2009) classic study looked at how psychoanalysis entered the French public and provided new interpretations of everyday behaviors (e.g., repression, Freudian slip, and unconscious), which were nonetheless constructed on the foundation of

existing ideas (e.g., Catholic confession’s “talking cure”). To take another example, Einstein’s theory of relativity has been generative not only for physics but also popular culture and many different fields of thought. In short, contact of groups brings into stark relief the possibility of doing things otherwise and thus opens up culture to new developments and imaginations for the future.

Minority Influence and Social Change

Social change often occurs when people are confronted with an idea that ruptures their taken-for-granted assumptions about the world. Suddenly they become all too aware that things could be different. What was earlier unquestioned becomes simply one *possibility* among others, which can require a cognitive effort to reestablish stability. This happens when one encounters unfamiliar or novel ideas and practices but can also be deliberately employed by a minority in order to change the perspective of a majority. Most psychological research on social influence has a “conformity bias” in that it focuses almost exclusively on how a majority suppresses a minority from publicly expressing their position, thereby sidelining the issue of how the minority can influence the majority, opening up the possibility for social change (Moscovici 1976a). In a famous experiment, Moscovici, Lage, and Naffrechoux (1969) demonstrated that minorities could exert influence on a majority by consistently presenting a different perspective on reality. In their experiment, participants had to call out when colored slides were blue or green. The slides were unambiguously blue to most. However, in the experiment a confederate minority (which were two out of the six in the group) said green, 8% of the real participants began to do so as well.

Minority influence has a deep-seated and private character, in contrast to the public conformity that results from majority influence – in other words, it is about *conversion* rather than *compliance*. Central to this theory is the idea that a minority that communicates with a persistent, consistent, and flexible “behavioral style” creates

a *tension* in people that are following the majority opinion. It causes them to look more closely at the minority's perspective, to try to see the world from their point of view. In other words, it can generate reflection on one's own position as being one among other *possibilities*. This tension becomes a "conversion" through a latent, unconscious process, usually after a "sleepy effect." In this way, even an initial active resistance to an idea – as opposed to simply ignoring or outright dismissing it – can be productive of change. In Moscovici et al.'s (1969) original study, participants that called out green in the trials actually showed a *lesser* shift toward calling out green on a color spectrum when compared to those that did not. This can be explained in that by publicly calling out "green" participants partially released the cognitive tension. Similar processes of intentional influence aimed at social change are often deliberately employed by protest movements.

Protest Movements as Catalysts for Change

One platform on which minorities extend the reach of their communication is through social movements. In particular, protests are a direct way of expressing civil discontent and creating imagery for social change in the form of slogans and pithy formulas. Protests are often triggered by immediate events in the present – comprehended within the collective memory of citizens – but are simultaneously informed by our imaginings of possible futures (Power 2020b). For example, during a recent protest movement in Ireland people protested during a stark economic recovery, following an economic recession, when a discrepancy between their expectations of the future did not align with their subjective reality – a timing that would be predicted by relative deprivation theory (Stouffer et al. 1949; Power et al. 2020).

The protest was proximately triggered by an introduction of a new charge on water which was seen by some members of Irish society to disproportionately impact working-class households. Similar dynamics can be seen in other protest movements, such as a gas tax triggering the

yellow vests movement in France (Jetten et al. 2020; Shultziner and Kornblit 2020). Interviews with Irish protesters revealed they were demonstrating because of the charge on water, which was understood within the cultural and historical context of rising inequalities, but was also firmly grounded in people's imaginings of the future (Power 2018b). Groups of Irish citizens imagined an economic recovery that was relatively equal but this possible world did not manifest which lead to a prolonged social movement and ultimately resulted in the abolishment of the water charge (Power 2018a). One reason for the demonstrable success of this social movement – from the point of view of those who protested – was the prolonged nature of the protest coupled with consistent messages and general widespread support for the clear cause. Another reason is that water acted as a concrete symbol from which to orientate a protest movement (Awad and Wagoner 2018). Moreover, the irony of having to pay for water in a small island, covered in lakes and rivers, where it frequently rains, was not lost on the demonstrators.

Similarly, the Arab Spring was triggered by the self-immolation of the street vendor Mohammad Bouazizi, whose cart and therefore livelihood was confiscated by a corrupt police officer when he would not give a bribe. The story resonated with a wider public that was experiencing economic inequalities, corruption, and a shared imagination of the perennial continuation of these problems (Awad and Wagoner 2020). It set off widespread social movements against a continuation of an unfair, corrupt, and unequal status quo across the Middle East. Its results, however, have been mixed. Tunisia saw some democratic reforms, while a brief period of meaningful democratic change in Egypt was followed by an even harsher dictatorship than before. This can be explained by a discrepancy between the rate of political change being incongruent with deeper levels of psychological change among citizens (Moghaddam and Hendricks 2020). In Syria, the Arab Spring culminated in a civil war between the government and those fractured groups who opposed them. The backing of both sides by international allies plunged the countries into a decade-long conflict,

with scores dead, lives altered, and mass migration of those seeking asylum and refuge. Imaginations of possible futures are not real, but their consequences are (Zittoun and Gillespie 2015). We also see the gap between the *possible* and its actualization here; reaching the possible is by no means inevitable. Following democratic revolutions societies typically fall back into dictatorship, and even established democracies tend to “commit suicide” in the long run to quote John Adams (Moghaddam 2016).

Finally, dystopian imaginings of possible future worlds also motivate protest movements in different domains. This has long been the case with regard to the environmental movement (Harré et al. 1999). The recent youth-led protest movement “#FridaysForFuture” was triggered by activist Greta Thunberg protest outside Swedish parliament who was dismayed against political inaction to mitigate climate change. This environmental movement spread globally. In neighboring Norway, for example, multimethod research with high school demonstrators suggests that a violation of shared visions for these youths’ future motivated protest in the present to enact impactful sociopolitical change to curb disastrous climate change and to preserve their preferred possible future (Haugestad et al. 2021). Like #FridaysForFuture, Extinction Rebellion and Sunrise Movements have also used apocalyptic imagery of the future and story scripts to press for action. Protestors stage “die ins” and other means of enacting dystopian futures to fuel the collective imagination for these impending threats. Like the Irish water tax, these devices help to condense complex and dynamic processes into relatable symbols (Awad and Wagoner 2020).

Problems and Paradoxes of the Possible

The Arab Spring revealed problems and paradoxes with imaginings of possible futures. First, there are as many possible futures as there are people to imagine them. Making manifest possible futures brings into focus issues concerned with power and representation: Who gets to communicate possible worlds? Who has the power to create these

possible worlds? Leaders have long known the destabilizing power of alternative ideas for the future. Retaining control is partly a matter of claiming exclusive rights to a narrative for the future. Second, the Arab Spring focused attention on morality and possible worlds. Imagining possible futures opens up space for how future societies *could* be in a descriptive sense. But how these societies *should* be, from a normative perspective, creates problems and paradoxes as well as possibilities.

Reducing economic inequalities, having fairer and less corrupt societies, and ensuring sustainable environments are worthy goals from a progressive point of view. Complexities arise when one comprehends the moral dilemmas, power dynamics, and resistance to forces advocating for these forms of social change. First, is it morally permissible to break the law to create social change? Second, we know people can protest to create social change, but how do authorities respond to demands for social change (Cornish 2012; Power 2020a)? And third, when certain individuals and social groups achieve social change that benefits them, to what extent do they advocate for social change that benefits others and to what extent do they now maintain the status quo?

Answers to these three questions lie within the moral domain. Moral pluralism – the heterogeneity of normative viewpoints – defines the splintering of possible worlds (Gray 2020). In response to the first question above, based on moral viewpoints, breaking the law is morally permissible if the law is deemed unfair, unjust, or illegitimate. Young Egyptians disobeying government laws to protest against the dictatorship is one example. Second, given moral orientations, Egyptians demonstrated on the street to help create space for, and make manifest, a fairer, more just, and equal Egyptian society congruent with how they think it should be. However, this possible world contrasted sharply with those in power who valued the moral, social, and economic order in which they enjoyed the benefits of power. Egyptian protesters were met with harsh military reprisals when they took to the streets. The conflict can be conceptualized as a clash of moral visions for

possible futures. The manifestation of these moral clashes as an open conflict creates the potential for democratic change and the creation of more inclusive and equal societies because the hegemonic power of dictatorial government is challenged which creates the potential for imagining beyond current regimes and to realize these imaginings.

Finally, once social change has occurred for one group (e.g., a law or policy has been introduced that legitimizes the way of life, or cultural practices of a group, or creates more inclusive, fairer, or more equal societies), whether this group continues to advocate for more social change to extend policies, protections, and possibilities for living the good life for other minorities can also be conceptualized within the moral domain. Achieving social change can fulfill one's moral imagination: Possible future worlds have become realities. But social change can also illustrate the limits of one's moral imagination of the possible. Alternative futures can be seen as impossible and therefore not worth striving for. Social change may be followed by the maintenance of the status quo to protect the fruits of this change rather than advocating for new forms of system challenging behaviors. At this point social changes are well embedded in cultural practices and serve to stabilize social life against further change.

The generation of social change through protest is rife with problems, paradoxes, but also possibilities. Sculpting future worlds is steeped in issues concerned with morality, power, and representation of others. What is considered to be social change to create a more moral society can be considered immoral by another group. If you have a moral view that values globalism, marked by global trade, open borders and the free flow of people, and expansive civil liberties, then you are undoubtedly concerned the populist turn against these in recent years. If you have a moral worldview that values nationalism, then one welcomes these protectionist and conservative policies. The recent populist turn illustrates how democracies such as the USA can slide toward dictatorships (Moghaddam 2019).

Conclusion

Social change can occur through cultural contact, minority influence, and social movements. These processes create space for the possibility of future societies. But social change is not always social progress and the notion of progress itself is inherently bound up with different moral visions. There is no inevitable march toward actualizing the possibilities of Enlightenment values (Shweder 1991). And what is considered social progress from one perspective can be deemed social regression from another perspective. One way to conceptualize these problems of the possible is to comprehend these conflicting divergences through a moral domain. In globalized societies, characterized by cultural and moral splintering, imaginings of how societies could and should be create space for multiple possibilities. However, social change is often, though not exclusively, dictated by those with power and resources to define the narrative trajectories of these possible worlds. Yet despite the complex challenges faced by those striving for more utopian imaginings of current societies, social change can lead to social progress. Democratic, tolerant, sustainable, inclusive, and equitable societies can be developed from mundane to radical social change.

Social Entrepreneurship

Ryszard Praszquier¹ and Paige Munnik²

¹Institute for Social Studies, University of Warsaw, Warszawa, Poland

²School of Psychology, University of Buckingham, Buckingham, UK

Abstract

Herein, the concept of social entrepreneurship is introduced and characterized through a discussion of its origins and various definitions. Its pivotal characteristics are depicted, including the role of innovations, entrepreneurial spirit, and specific personality traits. Also discussed are various research results, which posit that social entrepreneurs build social capital while pursuing their novel ideas. This social capital ensures the

indigenous character of the instigated social change process.

This entry provides examples of social entrepreneurship from various countries and continents that address diverse and pressing social problems. It also introduces global institutions promoting social entrepreneurship. Finally, it suggests further research that would be beneficial in this field.

Keywords

Social change · Innovation · New ideas · Creativity · Entrepreneurship · Social capital

Introduction: Defining Social Entrepreneurship

The term social entrepreneurship is relatively new (introduced in the 1980s), although social entrepreneurs have been about, in various fields, since much earlier. In the Victorian era, Elizabeth Fry (1780–1845), a known social reformer, engaged in efforts to reform life in prisons by attempting to raise public awareness of the inhumane conditions within them and by initiating legislation that sought to humanize the treatment of prisoners – particularly females. Octavia Hill (1838–1912), a British social worker, was particularly concerned with the welfare of inhabitants of overpopulated cities, especially London. Thomas John Barnardo (1845–1905), meanwhile, was an Irish philanthropist, as well as one of the founding directors of homes for poor children. Earlier, in the Middle Ages, Doctor Durand de Saint-Pourçain, the French Bishop of Mende, and Philippe de Maizières launched Montes Pietatis, an institution that lent money to the poor without interest, although this institution did receive provisions on loan-based profits. Much earlier, Emperor Ashoka (born in 265 BC), known as Ashoka the Great, brought harmony and unity to India, proclaiming reforms while establishing an empire on the foundation of righteousness, indicating that his primary concerns were his subjects' moral and spiritual welfare and the sanctity of all human life (examples from: Praszkie and Nowak 2012).

Social entrepreneurs – educated or illiterate, regardless of their age or gender and independently of cultural context – address pressing, often intractable social problems and introduce novel, systemic, and durable solutions.

Origins

It is believed that the term *social entrepreneurship* (SEship) was coined in 1980 by William Drayton¹ (Sen 2007), who identified individuals being, on the one hand, committed to solving social problems and, on the other hand, pursuing their ideas with an entrepreneurial aptitude (Praszkie and Nowak 2012). Among the various definitions currently in use (Mair et al. 2006; Mair and Martí 2006), the definition used by Ashoka: Everyone a Changemaker – the organization of social entrepreneurs, founded by William Drayton – is seen as the most comprehensive (Bornstein 2004): Social entrepreneurs are individuals with innovative solutions to society's most pressing social problems.

In this vein, social entrepreneurs are characterized as (Drayton 2002, 2005; Hammonds 2005):

- Being able to generate new ideas to solve critical social problems
- Being creative
- Possessing an entrepreneurial personality
- Having the capability to envision the broad social impact of their ideas
- Having an unquestionable ethical fiber

Additionally, they also (Bornstein 1998):

- Introduce innovative ideas, opening up new possibilities
- Combine down-to-earth realism and visions
- Possess creative and extremely ethical problem-solving abilities
- Demonstrate total commitment to their social change ideas

¹The founding CEO of the global organization Ashoka: Everyone a Changemaker.

Martin and Osberg (2007) proposed a shorter definition; that is, social entrepreneurs are those who:

- Focus their efforts on highly disadvantaged, neglected, or underserved populations
- Aim to generate large-scale, transformational benefits for either a significant segment of society or society at large

Any pressing, intractable social problem can be addressed by social entrepreneurs, for example, aging, unemployment, women's equality, poverty, homelessness, children living on the street, children with special needs, people with disabilities, health, discrimination against minorities, trafficking of women and children, education, energy production and distribution, energy renewal, chemical dependency, sanitation, information and communication technology (ICT) exclusion, environmental concerns, peace and conflict resolution, or rural community development (Praszkier and Nowak 2012).

Ambiguity of Definitions

Due to the vast number of definitions currently in use (Mair et al. 2006), the understanding and importance of the concept of social entrepreneurship differ between people: Some view it as not-for-profit initiatives in search of alternative funding strategies or as management schemes that create social value, while others understand it as a socially responsible practice carried out by commercial businesses engaged in cross-sector partnerships, and yet others see it as a means to alleviate social problems and effect social transformation (Mair and Martí 2006; Dacin et al. 2011). Along these lines, some authors have proposed a more flexible explication of the concept: Social entrepreneurship means creating and pursuing social value through recognizing and exploiting untapped opportunities, accepting higher risk, overcoming limitations, and generating and engaging innovations (Peredo and McLean 2006; Mort et al. 2006).

Some authors have also suggested more comprehensive and/or simplified definitions, for example, that the term social entrepreneurship refers to “the pursuit of sustainable solutions to neglected problems with positive externalities” (Santos 2012), or,

even more simply: “New ideas that work” (Mulgan et al. 2008).

Despite these variations, “new ideas” and “innovation” are commonly seen as pivotal.

The Role of Innovation

The majority of social entrepreneurship definitions are focused on the innovative character of a social entrepreneur's initiative (Alvord et al. 2004; Dees 1998; Drayton 2002; Bornstein 2004; Roper and Cheney 2005; Roberts and Woods 2005; Martin and Osberg 2007). Kramer (2005) stated that the ability to find new ways of doing things is inherent in the definition of social entrepreneurship.

Entrepreneurial Spirit

Another pivotal trait of social entrepreneurs is their individual level of entrepreneurial spirit (Bornstein 2004; Mair and Martí 2006; Nicholls and Cho 2008), especially if viewed as an engine that propels much of the growth of the business sector, or as the driving force behind the rapid expansion of the social sector (Drayton 2004; Austin et al. 2006).

Social entrepreneurs are visionaries, are creative, and have the acumen for implementing their novel ideas in workable and durable systemic solutions (Praszkier and Nowak 2012).

Personality Traits

Social entrepreneurship requires a specific approach from committed people who have specific personality traits (Bornstein 2004; Drayton 2005; Martin and Osberg 2007; Light 2008). Some authors have gone as far as indicating that “social entrepreneurship is not so much about pattern-breaking change, but about pattern-breaking individuals” (Light 2006, pp. 47–48).

Another study showed that social entrepreneurs exhibit statistically significantly higher levels of creativity, risk taking, and need for autonomy than traditional entrepreneurs (Smith et al. 2014).

Comparing personality characteristics (Praszkier et al. 2009) between societal averages (1), social activists (2), and social entrepreneurs

(3), it has been shown that both groups — social entrepreneurs and the leading social activists (i.e., (1) + (2)) — differ significantly from the rest of society (3) in terms of seven specific personality traits:

- They have a higher level of optimism.
- They trust others more than the average person.
- They are more willing to take risks.
- They have wider individual support networks.
- They believe that change is possible.
- They have a propensity for cooperation.
- They have a higher ability to cope with adversity.

Social entrepreneurs (3) differ from social activists (2) in two dimensions:

- They have a higher readiness for risk taking.
- They have a much deeper belief that “things can certainly change.”

Some critics have cautioned, however, that “there is a cult of personality that focuses on individual traits such as achievement, motivation, tolerance for ambiguity, optimism, intelligence, talent, and so forth,” drawing attention away from “real” capabilities such as an “ability to sell an idea” (Light 2006, p. 48).

Examples of Social Entrepreneurship

Below are some examples of social entrepreneurs (from: Praszquier et al. 2010; Praszquier and Nowak 2012; Praszquier 2015).

David Kuria, Kenya

For years, the critical issue in the Kibera slum, which is the biggest slum in Nairobi (home to 800,000 people) and the second biggest in Africa after Soweto, was sanitation. With no toilets, human waste was packed into plastic bags and thrown directly into the streets. Top-down solutions failed (e.g., the efforts of UNICEF), as they violated both the taboos and the prejudices of the local people. Subsequent similar solutions resulted in growing resistance, eliciting a “they want to impose things on us against our will” response.

David Kuria,² an architecture alumnus, joined the community, which ultimately allowed him to develop a deeper understanding of the beliefs and habits of the local people. As both an architect (by profession) and a social entrepreneur (by spirit), he fostered many small group discussions, during which members of the groups drew illustrations of how they envisioned a public toilet “of their own.” This process helped to engage the community and led to identifying the power of bottom-up group activities. From all of the drawings, David Kuria put together a realistic architectural design and, in a group gathering, asked people if they wanted to build their dream toilet.

The response was enthusiastic, and after raising some seed money and through volunteer work from community members, David Kuria facilitated building the first toilet (in 2003). As an outstanding clean point, it featured a variety of add-on services, such as shoe and boot polishing, a soda machine, and a cafeteria; meanwhile, one wall was reserved for advertising. Additionally, the design allowed human waste to be transformed into bio-gas, which, in turn, could then be used by the local women to cook. Soon, the cleaning and shining of the toilets became the community’s social focal point. This very quickly became a topic of interest for the media, who began covering stories of Kenyan VIPs having their shoes polished during a visit, for example. Later, the community members decided to impose a fee for the use of their toilets and showers, including a one-month family discount rate. Off the back of this, these facilities quickly became trendy, ultimately making the local people proud of their community and triggering many other business initiatives, thereby highlighting the positive impact of David Kuria’s project in terms of strengthening and empowering the social capacity of the community.

After building the first three toilets in the Kibera slum, which proved hugely successful in terms of improving both the hygiene and the dignity of the residents, David Kuria is now focusing

²See: <https://www.ashoka.org/en-us/fellow/david-kuria>, accessed 13 April 2021.

on replicating these facilities in various other slums around Kenya and beyond.

Dr. Yehudah Paz, Israel

Dr. Yehudah Paz,³ a social entrepreneur, is currently in the process of building islands of peace in the Middle East – a place where the basic currency of cross-ethnic relationships is distrust.⁴ Dr. Paz's core conviction is centered on mere conflict resolution not being enough, because peace leaves an unexpected void that people used to war very often find difficult to bear, especially if they are unable to perceive any other prospects. Based on this philosophy, he engages leaders from opposed groups in profitable joint ventures. Through cooperating in these ventures, Jews and Arabs are able to experience the great benefits that ensue from joining forces.

Peace imbued with new prospects results from this joint venture process, based on trust and success. Not only have new enterprises begun to blossom, but the empowerment of Arab women has quickly become a secondary effect; for instance, they have found themselves at the forefront of establishing new economic opportunities for both their families and their community at large. The structure of Dr. Paz's organization reflects the joint Israeli–Arab approach, which is jointly led by Arab and Israeli women, both of whom not only seed new concepts, but also serve as a model for change. By building bubbles of trust and cooperation, Dr. Paz is also preventing the potential outbreak of dormant conflicts between the two communities.

Dr. Paz's efforts began in the Negev Desert, involving Bedouins, Arabs, and Israelis, and are beginning to take root across the entire Middle East, as well as in Sri Lanka, Kenya, China, and South Africa. He calls his approach “integrated development,” combining trust, cooperation, and economic growth with education and orientation toward peace, yielding a widespread ripple effect,

which led to his characterization of the phenomenon as an “exponential spread.”

Krzysztof Czyżewski, Poland

Cross-ethnic, –religious, and –cultural conflicts impede economic development and fuel poverty in many places around the world that, in a feedback loop, accelerate conflict. Krzysztof Czyżewski, a social entrepreneur from Poland,⁵ demonstrated that using various small, community-based initiatives, rather than attempting to tackle an issue head on (e.g., through lecturing or patronizing society members), to address and overcome deeply ingrained cross-border and –religious prejudices can be far more effective. On the Polish–Lithuanian–Belarus border, which was previously considered an economically disadvantaged area, potential conflicts began to brew, with each group blaming the other for ongoing setbacks. Operating in this area, Krzysztof Czyżewski focused on restoring its historical roots by encouraging the local children to publish a chronicle and publicizing their efforts to collect and exhibit old photographs and postcards, as well as by tracing the area's multi-ethnic history. As a result, the region's historic Catholic, Jewish, Orthodox, and Protestant roots were rescued from the brink of obscurity and spread widely throughout the local communities.

Other initiatives involve teaching cross-cultural music lessons and traditional crafts, where young people are able to discuss the history and meaning of various traditions. Moreover, local youth, previously considered troublemakers and in conflict with mainstream society, are now engaged in efforts to revive indigenous Jewish folk music and they play in a Klezmer orchestra that performs both nationally and internationally. By transforming the perceptions and roles of young people within communities scarred by historical divides, Krzysztof Czyżewski is beginning to create a new vision for the future. This particular brand of entrepreneurship highlights the ability of small initiatives to accumulate

³ See: <https://www.ashoka.org/en-us/fellow/yehudah-paz>, accessed 13 April 2021.

⁴ See: <http://www.nisped.org.il/>, accessed 13 April 2021.

⁵ See: <https://www.ashoka.org/en-us/fellow/krzysztof-czyzewski>, accessed 13 April 2021.

and foster a shift in the collective mindset of a community, thereby eventually engendering social and economic development. This approach has been instrumental in preventing potential outbreaks of underlying cross-ethnic conflicts.

Asad Danish, Afghanistan

Asad Danish,⁶ operating in the Afghanistan Pashto tribal belt, is bringing about harmony and education through publishing and disseminating resources to illiterate people via the radio. He is mostly recognized for his publishing house, Danish Publication Association, which translates books, encyclopedias, and magazines into Pashto and then prints and disseminates them.

The foundation of Asad Danish's idea for social innovation is the creation of educational hubs based in small-town libraries in Afghanistan (mostly located in schools for girls and boys); he created the concept of the "dynamic librarian," enhancing the role of librarians and empowering them to create, host, or develop reading circles to promote education in local communities. To provide educational resources on various levels, Asad Danish's Danish Publication Association donates diverse books and magazines to these libraries. Moreover, he is in the process of establishing an FM channel that broadcasts local news and promotes Afghan culture and literature.

Through this approach, Asad Danish is building bubbles of harmony and peace, especially around "dynamic libraries," as people are gathering, reading, exchanging thoughts, and learning about other cultures. However, the impact goes far beyond education, such as promoting peace, understanding of other cultures, and tolerance.

Wannakanok Pohitaedaoh, Thailand

Wannakanok Pohitaedaoh,⁷ from Thailand's unrestful region of the Deep South, which frequently faces attacks from Muslim terrorists, became preoccupied with the ever growing number of orphans and child victims, often

traumatized after witnessing family members being killed. She was especially concerned about the lasting disempowerment and marginalization of victimized children, even if they had been taken care of.

When contemplating the root causes, she focused particularly on bringing peace to the region, paying special attention to the fact that external peace-building and conflict resolution initiatives (downward causation) are usually short-lived or even fail. Wannakanok Pohitaedaoh's overarching belief was that peace should be borne from within a community, rather than outside of it, and she decided that to achieve this, it was important to empower the orphans of the region to become a strong taskforce aimed at campaigning for peace and civic engagement. In this sense, the Deep South's predominantly Muslim community would no longer be passive, suffering such atrocities in silence.

This insight created in her enormous energy to empower and train these children, ultimately turning them into peace and civic engagement ambassadors. The biggest question, however, was around how this could be achieved, for which the answer was simple: Those who had experienced similar events should visit schools to share their stories and/or victimized families to share experiences and support, which would not only be cathartic for them, but would also inspire the next generation. Additionally, both publishing and disseminating their objectives could help to raise awareness.

Following this, Wannakanok Pohitaedaoh's next insight was that without strong civic engagement to combat terrorism, peace might not be achievable or sustainable. Thus, her idea was to engage and support young ex-victims in participating in communal and social problem solving, thereby establishing a civic engagement paradigm and demonstrating that power is found in a peace-oriented majority, not in terrorism. This idea proved successful in terms of seeing young people taking action to resolve many issues, such as solving local conflicts, participating in local elections, and helping to build local wells and roads. In this sense, these young people became community role models, particularly through their ability

⁶See: <https://www.ashoka.org/en-us/fellow/asad-danish>, accessed 13 April 2021.

⁷See: <https://www.ashoka.org/en-us/fellow/wannakanok-pohitaedaoh>, accessed 13 April 2021.

to instigate and instill civic activity (building an alternative attractor). Ultimately, the cumulative effect was the emergence of social capital, thereby both engaging and empowering the community to fight terrorism, which often meant standing up to their own neighbors. This type of bottom-up dynamic peace process is not only durable, but is also sustainable as it is supported by endogenous social capital.

Wannakanok Pohitaedaoh was able to trigger a bottom-up movement (upward causations) with multiple lower-level interactions based on minimal financial investment; this resulted in the emergence of social capital and a peace process on a higher level. By facilitating this process, Wannakanok Pohitaedaoh's aim was to provide power to others from behind the scenes (i.e., the absence of controller). Her intention was not to push or pull people or to influence their actions, nor did she want to attract fans or followers based on her charisma; instead, she wanted an autocatalytic process that benefited from the leverage points that she was able to build up.

Social Entrepreneurs Build Social Capital

As discussed, Wannakanok engaged in building social capital, which supported her mission. It has been documented (Praszkier et al. 2009; Zabłocka and Praszkier 2012) that social entrepreneurs are able to empower individuals, groups, and societies, alongside the pursuit of their social mission, through building trust and propensity for cooperation, that is, social capital (Bourdieu 1986; Coleman 1990; Putnam 1993, 2000).

Social capital refers to an important asset developed by a person's family, friends, and/or associates and is something that can be relied on in a crisis or enjoyed for its own sake (Woolcock and Narayan 2000). This asset is based on cooperation between the members of a society, a family, or a peer group (Bourdieu 2003).

Social capital provides important value both for individuals (Coleman 1988; Brehm and Rahn 1997; Burt 1997, 2001; Adler and Kwon 2002) and groups or societies (Woolcock and Narayan 2000; Fine 2001; Praszkier et al. 2009). Moreover,

many authors have highlighted its importance for community development and economic growth (Putnam 1993; Neace 1999; Maskell 2000; Fukuyama 2001).

Social capital supports and transforms a social entrepreneur's initial idea into an indigenous process, in which groups and communities identify and take co-responsibility for pursuing change (Praszkier and Nowak 2012).⁸ Additionally, social capital helps make the most difficult challenges achievable (Coleman 2000; Putnam and Gross 2002).

Promoting Social Entrepreneurship

Ashoka: Everyone a Changemaker

The creator of the concept of social entrepreneurship, William Drayton,⁹ is also the founding CEO (in 1980) of the organization Ashoka: Everyone a Changemaker,^{10,11} which is "pioneering the field and identifying and supporting the world's leading social entrepreneurs."¹² During its first 20 years, Ashoka selected, for its Fellowship, more than 3700 social entrepreneurs across more than 90 countries.¹³

"Ashoka has built and nurtured the largest network of leading social entrepreneurs in the world. After a rigorous selection process, individuals are introduced to a life-long fellowship, where every member is committed to championing new patterns of social good".

"Support provided for Ashoka Fellows include:

⁸ Along these lines, an evaluation tool was developed, measuring the propensity for building social capital (Zabłocka et al. 2016).

- A tailored stipend for up to three years, if needed, for the Fellow to dedicate themselves full time to the advancement of their idea;
- Customized engagement opportunities that accelerate their impact;
- Increased visibility;
- A global community of peers.”¹⁴

According to an Ashoka longitudinal survey, 92% of Fellows reported that the Ashoka stipend helped them focus on their idea full time. They also reported collaborating or partnering with at least four other Ashoka Fellows after being selected. This is possible through the Ashoka global network, which encourages Fellows to apply their work at a systems change level.

Schwab Foundation for Social Entrepreneurship

In 1998, Hilde (Chair) and Klaus Schwab founded the Schwab Foundation for Social Entrepreneurship,¹⁵ which has supported over 300 social entrepreneurs (as of 2018) to improve the lives of more than 622 million people across 190 countries.¹⁶

Summary and Conclusions

The field of social entrepreneurship is relatively new. As it intersects numerous domains, such as social innovation, nonprofit management, and entrepreneurial studies (Dacin et al. 2011), there is an ongoing debate over the definition and specific traits of social entrepreneurs, as well as over the methods to evaluate their impact.

The before-cited examples illustrate the significance of the innovations of social entrepreneurs, especially in the fields of peace-making, conflict mitigation, education in disenfranchised areas, and sanitation. When there occurs multiple pressing social problems, social entrepreneurs bring

systemic solutions to combating hunger, paving the way for equality, implementing renewal energy, preventing dependencies, etc.¹⁷

Social entrepreneurs occur everywhere, regardless of the conditions or context, such as high in the Himalaya Mountains (e.g., Lucky Chhetri from Nepal, empowering and educating girls from high Himalayan villages to become trekking guides¹⁸), among nomadic African tribes (e.g., Dennis Ole Sonkoi from Tanzania, bringing economic growth to Maasai people, based on their indigenous culture¹⁹), and in the poorest Latin American regions (e.g., Olga Bocarejo from Colombia, developing waste banks where children and youth receive food and nutrition in return for collected waste²⁰), as well as in the developed part of the world (e.g., Dr. Frank Hoffman from Germany, who introduced a solution for the early identification of the smallest nucleuses of breast cancer, through training visually impaired women, whose sense of touch is much higher than the average²¹). Common for social entrepreneurs is the use of imagination, which enables the establishment of possible, though previously unnoticeable, solutions (see: Glăveanu 2018).

The aforementioned finding, that social entrepreneurs pursue their innovative ideas through building social capital, indicates that they do not act single-handedly; on the contrary, they inspire groups and networks through creativity, empathy, and cooperation.

Social entrepreneurship seems an important contribution to solving pressing social problems and, as such, is worth further study. The key concepts to be explored include identifying specific approaches used by social entrepreneurs, how they enlist key local players and turn their

Socio-cognitive Conflict

Anne-Nelly Perret-Clermont

University of Neuchâtel, Neuchâtel, Switzerland

Abstract

The term “socio-cognitive conflict” has been coined to label a cognitive conflict experienced by two persons here and now and resolved socially, that is, a dynamic process that is elicited when different (initially incompatible) points of view have to be coordinated in order to find a solution that is acceptable for all partners (Doise et al.: *European Journal of Social Psychology*, 5(3), 367–383: 1975; Mugny et al.: *Bulletin de psychologie*, 321(29), 199–204: 1976). This coordination might be silent but most often takes the form of gazes, gestures, joint actions, verbal exchanges, or argumentation. Of course, the conflict is not always perceived as such nor is it always happily solved. This requires joint attention to a common object, mutual respect, and a “thinking space” sufficiently secure (emotionally, relationally, institutionally, and culturally) for the growing child, or for the adult learner, to dare explore alternative views while still preserving basic identity needs. Empirically studying socio-cognitive conflict is a way to observe the emergence (the genetic moment of “rising”) of a given, momentary (and, under certain circumstances, soon to be stable), new “possible”. It calls attention to the transformative and inventive (not only reproductive) experiences of knowledge

construction: it is possible to learn even without an expert on board. It opens the way to educational designs developing the skill to confront, reflect, and imagine alternative possible worlds.

Keywords

Socio-cognitive conflict · Perspective taking · Thinking · Development · Learning · Conceptual knowledge · Social interactions · Dialogue · Intersubjectivity · Cooperation

Synonyms

Conflict of centrations; Conflict of perspectives; Social cognitive conflict.

Introduction

Inspired by both Piagetian developmental psychology and social psychology, initial investigations on socio-cognitive conflicts were first conducted in children, opening a field of investigation known as “genetic social psychology” (Psaltis & Zapiti, 2014). Its first findings (see Perret-Clermont, 1980; Mugny et al., 1981; Doise & Mugny, 1984) concerned mainly the impact of such confrontations on the cognitive development of the individual partners. They evidenced that the need to (try to) reach a joint agreement necessitates and gives rise to an integration of the different views in a new cognitive organization at the collective and the individual level. In Piagetian terms, this meant that socio-cognitive conflicts were observed to be occasions for the children involved to move to a more advanced operatory stage, because of the cognitive restructuration that the *here-and-now* encounter with a dissenting peer had required.

This fact established that further research looked into the conditions under which socio-cognitive conflicts in children and adults are likely to occur and then on how they are solved with or without cognitive gains. As research developed,

in the laboratory and in the field, with varying methodologies, the discussion extended to different levels of analysis in order to account for the communication processes involved; the construction of the intersubjectivity between the interlocutors (not only peers but also experimenters gaining the research status of interlocutors); and the role of institutional settings, social representations, norms, and signs in framing the thinking spaces and the conversation modes.

Beyond the implications for psychology, educationalists (in schools and in vocational training) have been interested in the meaning of these findings to design activities that offer participants opportunities not only to learn about already established knowledge, but also to develop as creative thinkers exploring new ideas and (co-)constructing their minds. In such a perspective, children and adults (including researchers) are not only adapting to the world (and to knowledge) as it is (or seems to be), but they are also developing the possibility of confronting, reflecting, and imagining alternative perspectives, alternative possible worlds (Iannaccone et al., 2019).

Opening the Possible in Terms of Cognitive Growth

The concept of socio-cognitive conflict describes moments during which thinking is an activity that is simultaneously social and cognitive, open ended, and susceptible to leading to reasonable resolutions. Socio-cognitive conflicts can lead to learning gains not explainable in terms of imitation, tutoring, or social influence: hence, they allow for a type of learning that is a matter not only of appropriating existing knowledge but also of creating new understandings. This prevents learners from being reduced to the status of targets of transmissive actions via an asymmetrical power game. They are now observed as (co-) authors of their own development and engaged in making sense of their social and material world in order to transform it or to adapt to it.

What happens when two people have conflicting views on a precise matter and, not

withstanding that they are both convinced of their standpoints, they nevertheless accept to respect and explore the others' perspectives (see perspective taking) in order to establish if they can make a decision based on a shared understanding? Such a process does not necessarily presuppose that one is "right" and the other "wrong", nor that each one has a part of the "truth" and that a mere addition of their perspectives will lead to the solution. It is simply an open situation of unexpected cognitive conflict that obliges each interactant to become aware that a different perspective on the same common issue exists, embodied, here and now, in another person. When a common decision is needed and the emotional situation is safe, it encourages the interlocutors to make efforts to decenter from their own perspective. The fact of having to acknowledge this divergence without having to comply to the other's opinion opens *possibilities* for thinking because it leads the interlocutors into questioning (openly or silently) their premises: Why is the interlocutor saying this? Why is one partner not understanding what the other is saying? Isn't it evident? Is it possible to defend and coordinate these varied views and arguments to move beyond the dissonance that they create? Of course, on the way, the partners in the discussion might discover that they do not share common ground. But this will appear only if there is a socio-cognitive conflict that raises the issue.

The cognitive process elicited thereby is a complex one. It is dynamical, requiring distance from one's initial position in order to place it in a larger scenery that includes the other's position. This opens the possibility of creating new perspectives; it is a social and dialogical process. It requires open-ended (and sometimes partly implicit) argumentation based on the presupposition that a possible common answer is probably not known yet and has to be constructed and defended.

"Each possible is the result of an event that has produced an 'opening' within itself i.e., a 'new possible', that in turn, if actualized, will create new 'openings' on other possibilities" (Piaget, 1976, p. 282, our translation). What might be

confusing in Piaget's approach is his (over)-emphasis on the logical side of actions, tasks, and interpersonal coordination. But his inspiration can be useful in conducting minute descriptions of logical reasoning in interaction and in particular in conflictual intellectual interactions (Schwarz et al., 2008). They shed a new light on the interdigitation of social, cognitive, and emotional processes and on how they weave the material and symbolic context that they are part of (Grossen, 2001).

Genesis of the Concept of Socio-cognitive Conflict

Why was this concept proposed? In the 1970s, in schools, in academia, and in politics, the debate was hot between proponents of different types of explanations of why learning was (un)happily affected by social processes. The most widespread expectation of teachers was that they had to present proper models to their students, who would then learn by imitating (or memorizing) them adequately. The transmissive model was predominant, with a static understanding of what knowledge is and a prescriptive view of teaching. Most teachers had no experience of how knowledge is produced. Social class differences in school failure were reported by sociologists and known by the public. They were commonly interpreted as "socio-cultural handicaps" (whatever this meant). Some years later, these social representations of intelligence, learning, and teaching became an object of research (Gilly, 1980; Mugny & Carugati, 1989).

Academic empirical research already had a century of experience addressing issues of intelligence, learning, and development in different languages. But in the general context of the Cold War, the different theoretical lines developed in the East and the West tended to ignore each other. In Geneva, a younger generation was eager to recover this multidimensional heritage and debate, reading Piaget, Mead, Wallon, and the first available translations of Vygotsky. They had urged Piaget to create a chair of social psychology.

He had invited Serge Moscovici, Claude Flament, and then Willem Doise. It is in this very specific context that a new line of empirical investigations started in Geneva, concerned with the role of *socio-cognitive* conflicts in the development of the mind.

The notion of “conflict” is central to explain development in Piaget’s theory. Bärbel Inhelder was launching innovative research projects in order to provide descriptions of how children face cognitive conflicts in various activities and learn from this “micro-genetic” experience (Inhelder et al., 1992). She was careful to distinguish the two types of conflict and of learning. In type 1, there is tension between what is expected and what happens: children (because of their action scheme or representation or hypothesis) have an expectation that is partially or totally contradicted by their observations; this creates a disequilibrium, a kind of intellectual dissatisfaction. In type 2, children are experiencing two contradictory expectations because of two different schemes (or hypotheses) that are opposing each other. A very puzzling situation. The concept of “socio-cognitive conflict” was then introduced to draw attention to the social dimension of these conflicts: the cognitive contradiction experienced by the children usually takes place during a joint activity or a conversation. If they interiorize this social experience, they can reflect on it. Hence, it is central to investigate the role of the alter in such situations. Smedslund (1966) made the case that “conflicts of communication” played a key role in development. Empirical studies were needed to exemplify Smedslund’s assertions and to examine under which conditions the alter did not need to necessarily be a more expert person but could be a peer who is just as ignorant (see ignorance). This was the task of the first experimental studies of socio-cognitive conflicts. Later on, Kohler (2020) will describe the complexity of these socio-conflicts that occur often simultaneously on different planes and in interdigitated ways, for instance, when students, among themselves or with a teacher, discuss a problem in physics: they hold different perspectives, past experience, semiotic resources, motivations, intentions, and goals.

Research on Socio-cognitive Conflicts and Developmental Gains

The concept of “socio-cognitive conflict” has been used in quite a variety of lines of research, ranging from mere replication (or contradiction) of the initial results to raising fundamental questions in psychology, for instance: the difference between knowledge and social representations; the role of cognitive processes in social influence; the distinction between the psychological versus the epistemological subject; emotions and identity (Rijsman, 2004) as part takers in these socio-cognitive processes; asymmetric relations as limits to shared thinking. The concept of socio-cognitive conflict has also inspired innovations in educational design, in particular in cooperative activities (Roselli, 2000; Buchs, 2004), including computer-supported collaborative tasks aimed at learning through participation in argumentative conversations (Schwarz & Baker, 2017). In no way is it sufficient to just put children together to work around a task and see them progress. Due to a lack of space, the profound transformations that the educational strategy needs to undergo in order to take seriously into account the learners’ perspectives within the complexity of real field situations will not be addressed here (but see, for instance, Barth, 1994; Perret & Perret-Clermont, 2011; Kohler, 2020).

The proponents of the concept of “socio-cognitive conflict” had first to establish that socio-cognitive conflicts were observable and could be studied. Then, empirical research was needed to verify that the expected cognitive gains were developmental, that is, pertain to “deep learning” (operatory change) and are not mere repetition of expressions heard, imitation, or compliance. This was done starting with a four-step paradigm (pretest, interaction or control phase, post-test 1, post-test 2), inviting children to solve, alone or together, various problems in different experimental conditions. The two post-tests, generally conducted a week and then a month later, allowed a follow-up of the effect of the interaction in terms of learning gains and to assess their solidity. Perret-Clermont (1980) also used these post-tests to observe how the newly

developed concepts generalized to other tasks. This has evidenced a change of “structure” (as Piaget calls it) of the child’s mind, that is, a move from the initial stage of development (pre-operational) to the next one (operational). This was important because of the on-going debates around the distinctions between *surface learning* (retrieving information on the physical and social world and on one’s own actions, gained via observation or transmission from others) versus *deep learning* (developing internal operatory structures that organize the mind); adopting an *opinion* versus *constructing a concept*; expressing *one’s own understanding* versus *complying to the expectations* of a social demand. Piaget touched on this in the introduction to his 1929 book but had never investigated empirically the dialogical and methodological dilemmas that he highlighted there. This will be done in further development of the research around socio-cognitive conflicts (Sinclair-Harding et al., 2013).

In order to have a chance to video-record socio-cognitive conflicts, experimental situations were carefully designed with an effort to optimize the chances to generate such conflicts and their positive resolution thanks to a meaningful task with a common goal requesting a joint decision (e.g., a fair sharing of juice, the joint reconstruction of a village, etc.): children who didn’t know each other previously and, as a consequence, had no image of the partner’s “intellectual authority”; peers with different views according to the pretest but developmentally not too far apart in order to be able to understand each other; and a welcoming atmosphere (closer to play than to schoolwork). The positive results obtained with this initial design led to a systematical examination of the factors affecting progress after socio-cognitive conflicts.

Even a more advanced peer is likely to make developmental gains due to an interaction with a less advanced partner. This was the most striking result in the first generation of studies. Intermediate subjects are shown to progress even when they have been confronted with a non-conserver. Furthermore, in settings that offer different viewpoints (e.g., sitting at different places in the village task), children tend to have different

perceptions and progress even when they are similarly incompetent (Carugati et al., 1979). The incompatibility of their responses requires them to think differently. This finding was soon meticulously replicated by Ames & Murray (1982), and this process further investigated by others at different ages (e.g., Schwarz et al., 2000). Vertical relationships with authority figures are likely to induce the child into giving priority to the management of the asymmetry via obedience or compliance. Horizontal relationships – such as Piaget’s claim – are more likely to allow the child to focus on the task and its logics, and peer interactions are then more likely to support cognitive development. But experimental results report that being an adult does not make it impossible to have proper potentially fruitful socio-cognitive conflicts with children: this happens when an adult, in a not too “awkward” manner (Lévy & Grossen, 1991), gently contradicts the children’s assertions while helping them to maintain their attention centered on the cognitive issue (and not on an implicit power game). The beneficial social interaction does not require well-conducted explanations or sophisticated verbal productions. It does not even require a solution to be found on the spot. Being puzzled is essential. And this sets different socio-cognitive strategies on the move (Gilly et al., 2001; Laux et al., 2008).

Another set of results concerned children from disadvantaged backgrounds. Different studies, among which Coll Salvador et al. (1974), had shown that, even on Piagetian tests, at a given age, they are more likely to perform poorly in the pretest. This was replicated in the socio-cognitive conflict studies but only for the pretests because the amount of progress evidenced after the socio-cognitive conflict is such that finally, in the post-tests, their rate of success is similar to the children of more advantaged origin (Perret-Clermont, 1980; Mugny et al., 1981). This “recovery” is all the more remarkable considering that the phase of social interaction lasted only 8–15 minutes. Similar findings were found when comparing rural versus urban children (Nicolet, 1995) or boys and girls (Perret-Clermont & Schubauer-Leoni, 1981). In this last study, fine-grained analyses were conducted to understand

what was happening during the pretest that could account for these inter-group differences. They evidenced that middle-class children are more likely than the others to progress already during the pretest. Hence, pretests are not neutral. To middle-class subjects who remain centered on the cognitive issue (not being too intrigued by the social meaning of the adult's conduct or fearful of his judgment), they offer potential socio-cognitive conflicts via the adult's questioning (Lévy & Grossen, 1991). From there on, the classical four phases paradigm will be reconsidered as offering four events to the children forming a designed "experimental micro-history" (Perret-Clermont & Schubauer-Leoni, 1981; Tartas et al., 2016): the type of interpersonal relationship experienced during a phase affects the possibilities of the next phase not only because of the learning gains, but also via the transfer of social scripts, emotions, and interpersonal attitudes.

How Is the Socio-cognitive Conflict Resolved?

The replications and variations of these studies concerned, among others, the characteristics of the tasks including the norms and emotions related to them (Doise & Mugny, 1984; Nicolet, 1995); the institutional contexts (Iannaccone & Perret-Clermont, 1993); the material and social sources of feedback (Schwarz & Linchevski, 2007); the narratives justifying the action (Light & Perret-Clermont, 1989); and the social representations (Psaltis & Zapiti, 2014). These so-called "independent variables" are in fact dependent on how the participants interpretate the situation and their role and identity. This meaning-making activity will (or not) allow them to identify a conflict and engage in different strategies to solve it. A cognitive restructuring of the issue is not the only possible outcome, some social solution might be privileged (Sommet et al., 2014; Butera et al., 2019): children are alternatively likely to be overall concerned by being polite, honoring a friendship bond, saving face, winning what they (wrongly) perceive as a competitive game, or defending the (supposed)

prerogatives of their gender position. Researchers (and teachers) are quite likely to miss the fact that what the children are trying to manage is often not what they expect.

Conclusion

In education, as Grossen (2008) remarks: emphasis is often "put on mutuality, sharing, negotiation of a joint perspective or shared meaning, coordination, intersubjectivity, etc. All these aspects are indeed fundamental in communication processes but it should not lead us to ignore the fact that communicative processes are made up of convergences and divergences between the interlocutors, and that tensions (or conflicts) are part of any conversational dynamics" (p.248). Not only intra-mental processes are at work but also interpersonal ones. Facing disagreements in a constructive way creates new horizons for the thinkers. The concept of "socio-cognitive conflict" has called attention to the possibility that these tensions open for cognitive growth.

Research has explored the multiple conditions that must be fulfilled for socio-cognitive conflict to lead to better cognition. They concern the care to be taken in order to construct a "thinking space" (Perret-Clermont, 2015) sufficiently secure (emotionally, relationally, institutionally, and culturally) for the growing child, or for the adult learner, to dare explore alternative views while still preserving basic identity needs. The art of creating such thinking spaces awaits more contributions from educators, mediators (Greco, 2020), diplomats, and artists. Yazgi & Sandoz (2021)'s present participative theater play is a nice example of an invitation to decenter in order to invent possible solutions to tensions.

Space: Astronauts and Creativity

Henderika (Herie) de Vries
Yale University, New Haven, CT, USA

Abstract

Humans venturing into space require maybe more creativity and imagination, than any other human endeavor before. Creativity and space are inextricably linked. However, space has rarely been explored within the research domain of creativity. This entry presents a background of current knowledge for this possible future domain of research. On the one hand there is the existing connection of space and creativity, and on the other hand there are findings on human performance in space, which point to possibilities for research. Outer space represents an extreme human environment where creative thinking might sometimes be needed for survival. In contrast with general creativity research, space psychologists investigate human factors not in an optimal, but in an extreme environment. How does

human behavior and performance in extreme environments relate to creative potential and performance? Future answers to this central question will give insight into how to foster creative thinking also in extreme situations on Earth. Possibilities of future research directions are discussed.

Keywords

Creativity · Space psychology · Astronaut/cosmonaut · Environment

Introduction

Exploration of the universe was inspired by imagination long before humans flew into space. The space industry recognized from the beginning the role of creativity. Imagination in early science fiction stories inspired and served the development of space science before this was even technologically possible. A famous example is Jules Verne's "De la terre à la Lune" (French for "From the Earth to the Moon") (1866), which was translated to almost 100 languages from French. Another example is "Die Frau im Monde" (German for "The Girl in the Moon") authored by Thea Von Harbou (1929) who also consulted German rocket scientists for technical advice on accuracy.

Mathematics teacher and rocket scientist Tsiolkovski (1903) invented the rocket equation, which is a mathematical proof that a rocket can reach outer space. This "father of Russian space-flight" mentioned: "At first, we inevitably have an idea, a fantasy, a fairy tale, and then come scientific calculations." (in Siddiqi 2010, p. 16).

Creativity was seen as central in building the space industry. A US newspaper called a first NASA space object and communication satellite the "Echo balloon" (1960): "The visible symbol of American creativity for all the world to see" (p. 18, in Hansen 1995). It followed the first Russian satellite ("Sputnik," 1957).

More recently, former NASA administrator Mile Griffith, recognized that there are "real reasons" and official "acceptable reasons" to go to

space. Although official reasons involve the economy, policy rationales, military, scientific knowledge, and possible benefits for society, the real reasons that humans venture into space are curiosity, challenge and adventure, exploration and discovery, knowledge and inspiration.

There has been little attention within the research domain of creativity for space or other extreme environments (de Vries 2018, 2019). Creativity researchers naturally focus on optimal social, physical, and societal environments to foster creativity (Amabile 2013; Dul 2019; Harrington 2020), with exceptions (e.g., Simonton 2020). Possibly there were also practical reasons that "space" has not received much attention until now. To fund research on the psychological factors contributing to the creative performance of space travelers, an interest from the space industry for psychological research is also needed.

Although creativity was acknowledged in the USA as important for the space industry, for psychological science this was less so. This is best demonstrated by psychological selection criteria at the beginning of space flight. In the USA, astronauts simply had to demonstrate they had "the Right Stuff," of which courage and bravery were the main factors (Wolfe 1979). Flight crew of later missions were assessed on psychological concepts of "instrumentalism" and "expressiveness" and divided into categories with the "right stuff," "wrong stuff," and "no stuff" (Chidester et al. 1991; Santy 1994). Today selection is a more sophisticated process, and includes women with the "right stuff" as well (Weitekamp 2004).

The US space industry showed overall little interest in integrating psychology with astronautics, in spite of attempts from psychologists themselves (e.g., Smith and Altman 1961; Helmreich 1983). Psychology was at the time predominantly associated with psychotherapy and mental illness. The costly space industry needed to consider public relation effects to secure financial government support, and potential psychological problems could be interpreted as weakness and not project an image of strength (Harrison and Fiedler 2011). Psychological issues also represented a risk for disqualification for individual astronauts for future missions.

The culture surrounding the emergence of cosmonautics in Russia, the other “space nation” at the time, did allow for a natural integration of psychology at the service of spaceflight from the beginning (Petrov et al. 1979). For example, the Soviet head of space medicine mentioned already in 1980 that if there are limitations for humans in space, these are psychological, not medical (Vakoch 2011). According to space psychologist Vakoch, it was the joint cooperation of NASA of the USA and ROSCOSMOS of Russia with the cooperation of the Shuttle-Mir in 1993, and later the ISS missions, which spurred the incorporation of psychological knowledge for space.

But in contrast again with the USA, however, where creativity research evolved rapidly from the 1950s onward, in Russia there was less focus on creativity research related to psychological factors. Now that it is almost 60 years ago that the first human (Yuri Gagarin) flew into space, and the space community focuses on the journey ahead to Mars and beyond, creativity research related to space has become imminent (de Vries 2019). A reason for this is that deep space missions are characterized by specific and additional psychological challenges (Stepanova et al. 2003). The further into space human missions go, the more creativity-related skills will be needed to survive and thrive.

One possible challenge, for example, is the fact that the Earth will be seen as only a very small dot from Mars, if seen at all, and there is no possibility of direct communication with Earth and mission control, because of an up to 20-min delay in communication each way. It is unknown today what psychological effects this will have on the mental well-being of space travelers. Therefore, creativity skills, which are also related to well-being (Postareff et al. 2017) become increasingly important. To guarantee well-being on a Mars settlement, Russian space psychologists today recommend creative skills as selection criteria for future space travelers (Sal’nitakiĭ et al. 2003). This need is emphasized because of a shift of professional astronauts and cosmonauts to a diverse population of space travelers who will also settle on the Moon and Mars. While this entry is being written, a joint collaborative

mission of SpaceX and NASA, “Crew Dragon,” is flying the first two commercial astronauts to the ISS. Although the crew really consists of two experienced astronauts, future space travelers will be less trained and selected for optimal performance. Thus, insight into creative potential in outer space is needed, and it represents a gap in research.

A central question regarding understanding the relation between creative performance and the extreme environment of space is how the space environment relates to, and maybe alters, psychological factors which are related to creative potential. The next sections will first address the general domain of creativity and space and will be followed by a section on psychological factors regarding space travelers. Then, existing literature indicating possibilities of investigating altered creative performance, and recently suggested approaches for this new domain are presented. The overall aim is to integrate outer space and broaden the research domain of creativity.

Possibilities of Research: “Upstream,” “Midstream,” and “Downstream”

The first official space art piece is an aluminum statue of the “Fallen Astronaut” by artist Paul van Hoeidonck and resides since 1971 on the Moon. Space art is an elaborate field with a long history (e.g., Dougherty and James 1993; Malina 1991; Welch 2018). Malina subdivided art and space into domains such as “art about space,” “art sent to space,” “art created in space,” and “applied art.” The space industry regards the use of art as a powerful tool, and it acknowledges the importance of fostering the space industry.

Examples are the flourishing art programs of national space agencies in the USA (NASA) (Dean and Ulrich 2008), Europe (ESA), and Japan (JAXA). The importance of creativity for space was also reflected in the “NASA Institute for Advanced Concepts” (NIAC, 1988–2007). This institute provided an independent source from innovators, which impacted NASA’s missions, to develop new aeronautical and space concepts and encourage an atmosphere of creativity

and foster scientific innovation. Innovation remains central to investigate visionary far-reaching advanced concepts. For example, a recent book by the Innovation Director of NASA concerns artificial intelligence of the future (Hatamleh and Tilesch 2020). Further, there are art institutes such as “KOSMICA” (2011), which highlights in particular the intercultural, and interdisciplinary aspects of space.

Another way space is involved with the domain of creativity is through the field of primary and higher education. The study group “STEAM for Space” (2016) of the International Academy of Astronautics (IAA) is an example of a movement to support and encourage through space the fostering of creativity and art for science, technology, engineering, and mathematics.

Thus, space inspires creativity in the science of education, but it can inspire scientific creativity in all science research disciplines. The intercultural and international environment of the space industry represents an interesting context regarding creativity research. Furthermore, the interdisciplinary character of all space-related activities represents an advantage because it is known that this fosters creative thinking (Repko and Szostak 2020). The International Space University (Strasbourg, France), for example, integrates the following courses: Engineering, Space Applications, Human Performance in Space, Space Humanities, Management and Business, Space Policy, Economics and Law, and Space Sciences (Astronomy, Astrophysics, and Cosmology).

The science discipline this entry focuses on is creative human performance.

Creativity can be defined as: “The production of ideas that are not only novel – different from previous ideas in some way – but also appropriate: useful, valuable, correct, or somehow fitting to the purpose that the individual creator intends.” (Amabile 2018, p. 1). As Sternberg and Kaufman (2018) mention, creativity was for a long time thought of as ineffable, to be understood by examples of artists such as musicians, painters, or writers. But today, creativity is also researched scientifically as a psychological construct where it is regarded as a skill which can be learned,

assessed, and measured (e.g., Lubart et al. 2013; Barbot et al. 2016).

When we use a space analogy, endless possibilities appear to explore creativity and space. In the space industry activities are categorized into upstream, midstream, and downstream activities (PWC 2019). The upstream industry represents all objects sent into space, such as launching rockets. The midstream industry concerns all operations supporting both upstream and downstream aspects. A gateway, for example, serves to explore further into deep space, but also to return to earth. The downstream sector uses upstream and midstream products for all kinds of applications serving earth, such as climate change and public health (Space Safety Magazine 2014).

Taking this analogy further, research on space and creativity could evolve from an earth and reality bound (downstream), to a more abstract theoretical (midstream) and finally theoretical universe, which transcends time, space, reality, and existence (upstream). This means that all empirical research into the psychology of space and creativity for applications on earth would be called a “downstream” activity. A “midstream” approach represents theoretical support for applied research, which is however also embedded in larger philosophical ideas. The “upstream” activity concerns broader philosophical ideas. An “upstream” example is the theory on the dynamic nature of creativity (Corazza 2016).

Concerning “downstream” research, there are many gaps of knowledge regarding space- and creativity-related skills and only a few researchers touched upon this subject (King 1997; Schlacht et al. 2010; Kanas et al. 2011; Peldszus et al. 2014; de Vries 2018, 2019). White (2014) mentions general alterations of perception during a space mission. This includes altered perception of space, time, silence, and weightlessness. Within the multivariate theory of creativity (Sternberg and Lubart 1995) known psychological factors contributing to creative potential are personality traits such as “openness to experience,” conative factors such as “tolerance of ambiguity and uncertainty,” affect (emotions and moods), “motivation” and “risk taking,” knowledge (memory, attention, cognitive processes), and the

environment (context and culture). These factors might contribute (or impede) in different ways creative performance in space. To investigate this, first more understanding is needed of implications of the extreme environment of space on psychological factors and cognition. The following section describes this field of space psychologists.

Space Psychology

Space psychology is concerned with the well-being of space crews to optimally accomplish missions. A large part of the space industry consists of engineering, and this technological perspective is reflected in space life sciences as well. The human body and mind are sometimes viewed as “a very successful technical engineering project that is hard to replicate, and of which the detailed engineering specifications are not yet fully known.” (Damann 2009). To live and work in space, this human machine needs a specific environment, food, water, rest, and also mental health. The means of support for optimal accomplishment of missions are training, mitigation of risks, monitoring, mentoring, and developing countermeasures. A distinction is made between physical and mental requirements for: (1) suborbital, (2) orbital, and (3) planetary exploration crews (Clément 2011; Petersen et al. 2016). For the suborbital crew, the focus is on choosing humans who can mainly physically survive the particularly high acceleration during reentry, and those who can bear motion sickness. The orbital flight missions require additional selection criteria because of a range of physical alterations: e.g., bone loss, muscle atrophy, cardiovascular deconditioning, and disturbances of the vestibular system, causing misorientation. For this crew, there are also mental, or psychological, requirements because of the longer confinement and isolation. Finally, planetary exploration, like a settlement on Mars, requires extensive psychological criteria for crew selection, including creative skills, besides addressing health hazards (for an overview see Afshinnekoo et al. 2020).

Most astronauts and cosmonauts experience even on short flights “space fog,” a general term for cognitive issues, like difficulty of concentration, attention and memory, and slowing in general mental and motor functioning. What are the specific stressors causing psychological alterations? Before the effects of stressors are researched, they are identified and categorized. Space psychologist Kanas (2015) for example, divides known stressors into a (1) Physical stressors (periods of high acceleration, microgravity, ionizing radiation, meteoroid impacts, light-dark cycles, vibration, ambient noise, low and high temperature, diminished lighting, no air or poor air quality, psychological, interpersonal, and psychophysiological nature), (2) Psychological stressors (isolation and confinement, life-threatening danger, periods of monotony and high workload, time effects, personality and crewmember-selection issues, too much free time, increased autonomy, dependence on machines and local resources), (3) Interpersonal stressors (group size, limited social contacts and novelty, group heterogeneity, common language, cultural differences, governance structure, leadership roles), and (4) Psychophysiological stressors (sleep loss and changes in sleep patterns, disruptions in circadian rhythm, impairments in time sense, increased auditory and visual perceptual sensitivity, disturbances in spatial orientation, attention lapses, confusion, memory problems, psychomotor problems).

Others, such as biologist Whitely and Bogatyreva (2018) propose to systematically investigate possible human factors with their model of “7 protective shells and the environment,” where they combined insights from engineering and psychology.

The effects known today of psychological stressors vary from euphoria caused by microgravity to depression from living in a confined environment far away from home, neurosis, sharpening and accentuation of negative personality traits, effects of fatigue such as emotional instability, and psychosomatic dysfunction. Cognitive effects are, for example, diminished psychomotor, dual-task, tracking and fine-manual performance, as well as sleep-related impacts on alertness, response times, and ability to focus (for

an overview see Morpew 2001), and research is ongoing.

Current research on human performance concerns, for example, team selection (Maschke et al. 2011), conflict resolution, teamwork in confined spaces (Landon et al. 2018), communication with mission control (Gushin et al. 2016), circadian rhythm and human performance during space flights (Flynn-Evans et al. 2016), and studies investigating long-term postflight effects of values (Suedfeld et al. 2012). Other examples are human-machine interactions, eye tracking research, and thermal comfort (e.g., aircraft cabin, train).

The main and unanswered questions are how these altered human factors in space relate to creative performance. Interestingly, studies conducted in relation with creativity overlap issues studied in space. Examples are research on the relation between creativity and the circadian rhythm (e.g., Jun et al. 2019), teamwork and creativity (e.g., Reiter-Palmon 2017), eye-tracking and creativity (Agnoli et al. 2015), mood and creativity (e.g., Baas et al. 2008), and virtual reality (e.g., Guegan et al. 2017). It seems only a small step for creativity researchers to connect knowledge of creativity on earth to creativity in outer space.

In their excellent work, Russian space psychologist Sal'nitakiĭ and colleagues identified consequences of specific psychological challenges related to new expected stressors for a Mars mission. In their article written in Russian, they describe known psychological challenges caused by physical stressors, technical issues, and new possible stressors. The five new stressors are (1) transformation of the sociopsychological needs of the crew in an unpredictable direction, (2) sustained conflict tension in the crew, (3) an acute mental disorder in one of the crew members, (4) refusal of activity, and (5) difficulties of crew communication with representatives of ground services.

They also describe "mental asthenization." This is a condition based on increased fatigue, quick exhaustion of nervous processes, a decrease in the ability to prolong intellectual stress, not found in astronauts and therefore representing a

cultural difference in emotions (Kanas 2015). Cultural differences (Boyd et al. 2009) and emotions in space are rarely researched and represent a direction within this new domain.

Overall, there are many unknowns if the next goal of living in space with complete physical, mental, and social wellbeing is possible. The next section highlights some existing findings of research which indicates that creative potential might indeed be altered in the outer space environment. Finally, recent publications are mentioned of proposed models to study creative performance in space.

Space Psychology and Creativity

Will astronauts and cosmonauts in the future be selected, assessed, and trained for creative potential, as Russian psychologists suggest (Sal'nitakiĭ et al. 2003)? If this is indeed the future, it is relevant to investigate what are the unknown effects of the extreme environment on creative potential. Findings of existing studies give indications for future research.

A study by Suedfeld and Weiszbeck (2004) showed that astronauts and cosmonauts view the personal value of self-direction (Schwartz and Bardi 2001) as the third most important from 11 values. Self-direction is related to creativity. Research further shows that space missions can alter personal values and motivation. Suedfeld and Weiszbeck also found that for some early astronauts, the value of self-direction decreased during the mission, but after the mission it increased to a higher level than before the mission. A study from a simulation Mars mission by Sandal et al. (2011), with six analogue astronauts confirms the tendency that self-direction decreases during the mission. The authors also found that there was no indication of groupthink, but rather that values were related with the formation of groups. Group dynamics might therefore be different in space (Landon et al. 2018), and this raises the question if this also influences group creativity (e.g., Reiter-Palmon et al. 2012).

Does the extreme environment interact with other factors contributing to creative potential,

such as personality, or emotions? There are studies touching on this topic of salutogenesis or personal growth (Ritsher et al. 2007). Space psychologist Suedfeld et al. (2012) asked 20 cosmonauts, and as a control group new mothers, and a group of trauma survivors, to fill out a 21-item Post Experience Change Inventory. This Inventory is an adaptation of the Post-Traumatic Growth Inventory (PTGI) (Tedeschi and Calhoun 1996). The cosmonaut group scored significantly higher on the item “new possibilities” area of personal growth than the other two groups, after the mission. Although this is not a creativity measure, it could relate to an alteration in creative cognition as well. In again another study on personal growth, researchers (Ihle et al. 2006) found an interesting distinction in two groups of astronauts and cosmonauts. Participants (39) filled out 36 items of a questionnaire, the “Positive Effects of Being in Space” (PEBS) Questionnaire. This was again an “adapted for space version” of the PTGI. They found significant differences between a high- and low-change group. The high-change, and more reactive group, ranked higher for “excitement of perceptions of space” such as “a sense of wonder about the universe, space exploration, and appreciation of boundlessness of the cosmos.” The low-change, or low reactive group, ranked higher for changes involving their inner life. This group reported “a new appreciation of life,” “changing priorities,” and “a better appreciation of each day.” This finding is interesting considering that a main predictor of creativity is the personality trait of “openness to experience” (e.g., Dollinger et al. 2004). It represents a sensitivity toward fantasy, feelings, aesthetics, ideas, actions, and values (McCrae 1987), and as Eldesouky (2012) noted, all facets of openness can involve an inner and outer environment.

A common way to assess creative potential is to assess fluency and originality of divergent thinking. However, it is unknown how divergent thinking relates to differences in inner and outer facets of openness to experience. Research with space travelers might therefore offer new insights.

More cognitive changes are observed in astronauts and cosmonauts. An example is the experience the “Overview effect” (White 2014): “A

cognitive shift in awareness reported by some astronauts and cosmonauts during spaceflight, often while viewing the Earth from orbit, . . . the experience often transforms astronaut’s perspective on the planet and humanity’s place in the universe. . . Some common aspects of it are a feeling of awe for the planet, a profound understanding of the interconnection of all life, and a renewed sense of responsibility for taking care of the environment.” (p. 2). There is currently no knowledge of whether this transformative experience in space is connected to measurable cognitive changes related to creative potential. A recent study with an analogue “overview effect” on earth, the Space Buzz, did find indications of a cognitive effect for children (van Limpt-Broers et al. 2020).

Overall, the existing studies indicate that space might both impede and enhance creative potential. The overview effect could be related to developing a higher level of creative potential as does research on values in space. However, the condition of “space fog” might again inhibit creativity. Future research measuring creativity of astronauts before, during, and after space flight will shine light on and fill the “creativity and space” research gap.

Creativity researchers are starting to become interested in this new domain of creativity (de Vries et al. 2019), and propose theoretical models. Referring to the categorization earlier, these are midstream theories. Examples are Bourgeois-Bougrine’s (2020) theoretical model to investigate creativity in safety-critical environments, and the “Space art taxonomy model” of Hays et al. (2020), which distinguishes two dimensions of space art. One dimension is where the art is created, and the other where it is experienced. Another “midstream” model is the “Expansive Multiverse Framework” of creativity (de Vries *in review*), relating new sensorial experiences with a broadening of cognitive and emotional “universes” and creative potential.

An example of how “upstream” theories are related to “midstream” theoretical approaches is the application of the (upstream) “Dynamic creativity framework” theory (Corazza 2016) to (midstream) scientific missions (Corazza and Lubart

2020). Their Space-Time continuum model is built on the “Cultural Actuation Model” of creativity, a developmental model, which predicts more or less originality and fluency in divergent thinking, based on cultural differences in tolerance of ambiguity and other values (de Vries 2018).

Overall, there are many research gaps, or rather an unknown number of possibilities, related to open questions related to “downstream,” “midstream,” and “upstream” approaches, to explore in the future.

Summary

This entry covers a nascent domain of research.

Within the constraint of science on space and creativity, possible future domains of research emerge, which can be categorized in “upstream,” “midstream,” and “downstream” directions. Philosophical explorations surpassing boundaries of time and existence correspond to an “upstream” infinite realm. Theoretical “space” models supporting both philosophical and more practical applications are of a “midstream” nature. The subject as elaborated in this entry is an example of a “downstream” approach. However, a downstream application also forms the basis of the upstream and midstream research and in this sense, there is a circular and infiniteness as well to the quest for knowledge.

It was mentioned that a link already existed between creativity and space before humans flew into space. This is also reflected through the history and industry of spaceflight. Space psychologists identified stressors on humans during space missions to guarantee optimal mission accomplishment and the well-being of astronauts and cosmonauts. Specifically, Russian space psychologists recognized early on the importance of creative skills, also for long-duration missions.

It was suggested that changed psychological factors, which are known to be related to creativity on Earth and part of a multivariate theory of creativity, could be related differently to creative performance in space, as studies of space psychologists indicate. Examples are changed personal values, the overview effect, and salutogenesis.

With knowledge available on psychological factors of space and of creative potential, we can explore possible new dynamics of creative performance in space.

Insights into this new domain can serve training and selection practically, and help human space missions succeed. Creativity research in the extreme human environment of space also benefits the research domain of creativity, as it might even broaden the concept of creativity itself. An “upstream” idea is that scientific concepts such as creativity are bound by human understanding of nature (de Vries 2018). Maybe all our inquiries therefore ultimately serve humanity.

Or, in line with philosophers such as Nietzsche (1968) and as stated by Dr. Franco Malherba, the first Italian astronaut: “Man will never refuse the experience of travelling beyond the Pillars of Hercules to explore other worlds, as part of an endless quest to find himself.” (ESA 2015, p. 25).

Speculation

Arran Gare
Philosophy and Cultural Inquiry, Swinburne
University, Melbourne, VIC, Australia

Abstract

“Speculation” originally meant “reflective observation.” It came to mean “conjecture” or “mere conjecture” as philosophers strove for certainty, consecrating science as rigorously acquired knowledge accumulated through application of the scientific method, and devalued the cognitive status of other discourses. The present conventional meaning of

speculation, where the place of observation has disappeared, is a by-product of this consecration. In this entry I show how, through efforts to defend the status of these other discourses, the original meaning of “speculation” was not only revived but built upon by speculative philosophers. They showed that speculation is primordial to all experience and thinking, with past speculations embodied in language as “dead” metaphors. Revealing the possibility of elaborating alternative metaphors frees us from not only these dead metaphors to overcome the dead ends of current science, opening up new possibilities for enquiry, but the possibility of reconceiving ourselves and our place in nature. In this way, speculation makes it possible to transform ourselves, creating radically new ways of living and new forms of life. On this view, speculation, by opening new possibilities, could free us from the destructive trajectories of current civilization.

Keywords

Speculation · Scientism · Dialectics · Metaphors

Historical Context

Currently, “speculation” is taken to mean conjecturing without conclusive evidence, or the activity of proposing possible answers to questions based on limited knowledge or information. Tacitly, speculation is counterposed to knowledge based on practical experience, rigorous observation, or rigorous reasoning and is defined as inferior to these and not to be taken seriously. This everyday usage can be regarded as common sense, but it has not come to us through the evolution of common-sense. It is the product of a long history of philosophical disputes ramifying through the entire culture of Western civilization. The current meaning of “speculation” is inextricably linked to other concepts that also have gained their current meaning through equally long histories of philosophical disputes. The concepts of evidence, knowledge, and information are obvious examples. The word “speculation”

has its origins in the Latin *speculum* which meant mirror, reflection, and reflective consciousness and late Latin *speculationem* which meant contemplation or observation with the root *spek* coming from the proto-Indian-European, meaning “to observe.” So, originally “speculation” meant “reflective observation.” According to the Oxford English Dictionary (Speculation 1989), the original English word meant “To look or gaze at (something); to examine, inspect, or observe closely or narrowly” or “To observe or view mentally; to consider, examine, or reflect upon with close attention; to contemplate; to theorize upon.” In the mid-fifteenth century, “speculation” was taken to mean the pursuit of the truth by means of thinking, or thinking or meditating on a subject. Evidently, the place accorded to observation in speculation gradually dropped out. It was only later that “conjecture” became central to the concept and only from the late sixteenth century that speculation gained its disparaging sense of “mere conjecture.”

This disparaging sense gained momentum with the seventeenth-century scientific revolution and the quest for absolute foundations for knowledge and absolute certainty, whether through reason associated with mathematics, deductive thinking modelled on mathematical reasoning, or on what is immediately given to the senses. Most importantly, this revolution was associated with the differentiation of scientific knowledge from all other kinds of knowledge. This claim for scientific knowledge was consolidated in the nineteenth century through Auguste Comte’s positivism and in the twentieth century through logical empiricism and, more specifically, logical positivism. Logical empiricism was founded on empiricism and the newly developed symbolic logic and effort to provide absolute foundations for mathematics either through logic or through precisely defined formal rules of manipulation of symbols. Certainty could be achieved through a combination of induction and deduction. What was seen to be most important in theories is that they generated predictions that could be verified. Science was seen to advance by the development of more general theories able to deduce more particular theories as special cases, implying a deterministic

universe. The successful application of science to technology was a further way of validating scientific knowledge. While logical positivism has been severely critiqued in philosophy, it retains its hold on culture as justifying “scientism,” the belief that only science gives us real knowledge. Rather than sense experience or observational statements, it is common now to think that knowledge is certain because it is grounded in data, or information, allowing some role to conjectures in developing knowledge, provided these are not merely speculative and conform to measurements or statistical analysis of data. It is in this context that the pejorative sense of speculation has gained the status of “common sense.”

Such scientism has always faced opposition. The first major challenge to this conception of knowledge came from Giambattista Vico. Vico was proposing a New Science, characterized as “Speculative Geometry of the Civil World,” but essentially, he was upholding and greatly advancing the humanities and the traditions of rhetoric and history. Arguing that we can know the truths of geometry because we ourselves created it, he argued that the human world can be understood in its historical development because we created it. Because we did not create nature, we cannot really understand it.

Philosophers in Germany offered the strongest defense of speculation, however. Kant was their main point of departure. Like Vico, Kant argued that we can truly understand only that which we ourselves have created, with mathematics taken as a model for this. However, Kant also argued that all we experience is in some sense our creation, produced by synthetic thinking involving imagination, forms of intuition (space and time), and the categories of the understanding. What we observe is guided by questions formulated in terms of these concepts. Kant’s critical philosophy aimed to defend such conceptual knowledge, along with the principles of practical reason and aesthetic judgments of taste. This was neither analytic nor empirical knowledge, but *synthetic a priori* knowledge. Such knowledge would seem to require some form of speculative imagination to account for it. In *Critique of Pure Reason* (1996, A635f. and B663f., p. 612), Kant considered but

rejected this, characterizing speculation as a fruitless theoretical exercise in which cognition aims at an object, or concepts of an object, of which one cannot gain any experience. He invoked dialectics, but merely to show that it is impossible to choose between rival doctrines on issues central to traditional speculative philosophy.

This provoked a reaction, and it was through this reaction that speculation came to be strongly defended. Typically, G.W.F. Hegel defended speculative philosophy through dialectics. Dialectics as conceived by Hegel, under the influence of both Kant and Plato, has a negative side, as the way to expose one-sidedness of abstract propositions of understanding and how these necessarily veer into their opposites. Speculative philosophy was defended by Hegel (1975, §81, p. 115ff.) as the “positive” or speculative side of dialectics. It is the process of overcoming contradiction, one-sidedness, and differences to achieve more comprehensive knowledge, including self-knowledge. In the Preface to his *Phenomenology of Spirit* (1977, §61, p. 38), Hegel examined the claim to be able to ground knowledge on a foundation of sense-certainty, revealing this claim to be one-sidedness, leading through successively less one-sided “solutions” to the conclusion that “knowledge” cannot be treated in abstraction from self-understanding achieved through world-history. Building on the Socratic question that allows us to bring any aspect of experience before the mind and consider its being and meaning, he introduced the notion of the “speculative sentence.” While the Socratic question makes the mind dialectical, allowing it to move from one question to another, the speculative sentence, as interpreted by Donald Verene (2009, p. ix), “turns this series back on itself, revealing its pattern of self-development.” As Verene noted (p. x), “speculation excludes neither reflection nor analysis” but is the “logic of question and answer that is the key to philosophy, far more than argument. Anyone can argue, but few can ask the right questions.” While reflection and argument operate at a distance from the object, “[t]o speculate . . . is . . . to narrate the inner life of the object” (p. 3). As a speculative philosopher, Hegel was concerned to provide a systematic and comprehensive

understanding of human existence and its place in the cosmos, encompassing the natural sciences, history, literature, and art and revealing the possibility for freedom in how we live and organize society.

Hegel defended a form of Idealism, claiming that nature itself is a product of Spirit. Our knowledge of nature only reveals Spirit in nature. Idealism was common to many other philosophers opposing scientism. Subsequently, most philosophers abandoned Idealism, and along with it, speculative philosophy, and its quest for comprehensive understanding. Philosophy was then riven by the opposition between those with a primary allegiance to science conceived of as having found the way to acquire certain knowledge of reality, as with most analytic philosophers, or to the humanities often sympathetic to some form of Idealism. This opposition did not exhaust the traditions of philosophy, however. Other traditions, including most Marxists, pragmatists, and many phenomenologists, extolled practical knowledge over speculation. In some cases, these philosophers aligned themselves with science, as with orthodox Marxists, and in others, with the humanities, as with humanist Marxists, hermeneutic philosophers, and ordinary language philosophers. Either way, these philosophers also tended to dismiss speculative philosophy. The combination of scientism with the privileging of action over speculation led to the identification of knowledge with techno-science and the assumption that all true knowledge shows us how to control the world, including people, more efficiently. The only possibilities for the future are those which will be delivered by technology.

However, some speculative philosophers embraced naturalism, although often without being recognized for doing so. This was the case with Friedrich Schelling who explicitly rejected Idealism. They can best be characterized as speculative naturalists, upholding the ambitions of speculative philosophy and the conception of humans as essentially creative as defended by speculative Idealists while holding that nature preceded humanity and humanity emerged and evolved as participants in a creative nature. Aligning themselves with the humanities, they

challenged the characterization of science by its rationalist and empiricist defenders and their claims that science achieves indubitable knowledge and, following from this, challenged prevailing scientific theories. Embracing Kant's argument that all our knowledge of the world is organized by imagination and concepts, but rejecting his claim to have shown that only one set of concepts are coherent and thereby valid, they argued that existing concepts could be transcended. Attacking Newtonian science, for making sentient life and mind unintelligible, Schelling outlined a speculative physics that could replace Newtonian physics, revealing new possibilities for science that had a major influence on subsequent developments in physics, chemistry, and biology (Gare 2011).

Speculative naturalism was later revived and advanced by C.S. Peirce, Henri Bergson, and Alfred North Whitehead and their followers. Whitehead launched a particularly strong defense of speculative philosophy or metaphysics. While this tradition of speculative naturalism was eclipsed by logical empiricism and phenomenology within mainstream philosophy, and later by structuralism and poststructuralism, the ideas of these philosophers were kept alive among philosophers of science and sympathetic scientists. In demolishing logical positivism in the third quarter of the twentieth century, philosophers of science further developed their arguments, showing the central role for speculation in science itself. This again aligned science with the humanities and, along with granting a place to speculation in science, also gave a place to speculation in transforming humanity and creating the future. As with Schelling, these philosophers provided the means to defend the ideas of Vico and the speculative Idealists on naturalistic foundations. It is this tradition of philosophy that provides a real challenge to the denigration of speculation, and it is through their work that what is speculation can be characterized and defended and shown to be central to science as well as the humanities and everyday, practical life. Work in speculative philosophy or metaphysics has also been strongly supported within the natural sciences by theoretical scientists striving to overcome the heritage of

Newtonian science and its implicit assumptions and the failures of more recent physics. Such work has helped inspire what has been called the speculative turn in recent philosophy associated with speculative realism, speculative materialism, and speculative naturalism, with a revived interest in Schelling (Bryant et al. 2011; Gare 2011).

What Is Speculation

It is in the context of the original meaning of speculation, the change of meaning associated with the quest for certain knowledge, and then the reaction to this by speculative philosophers that its nature and significance can be understood. To begin with, the tendency to exclude observation from the meaning of speculation and then defining it as being in some way inferior to observation should be rejected. Speculation begins in reflective observation. Later efforts to revive and defend speculation have revealed new dimensions to such reflective observation.

Speculation potentially brings everything into question, beginning with appearances and beliefs, methods of inquiry and knowledge of methods for acquiring and ascertaining claims to knowledge, and, more fundamentally, the concepts which define domains for investigation and conceptions of subjects able to speculate. Speculation is not necessarily philosophical speculation; however, reflective observation challenges one-sided thinking and, if pursued long enough, almost inevitably leads to speculative metaphysics, or to sympathy for it. Whitehead (1933) characterized philosophy itself as "an attitude of mind towards doctrines ignorantly entertained" and in defending speculative philosophy argued:

No science can be more secure than the unconscious metaphysics which tacitly it presupposes. The individual thing is necessarily a modification of its environment, and cannot be understood in disjunction. All reasoning, apart from some metaphysical reference, is vicious. Thus the Certainties of Science are a delusion. They are hedged around with unexplored limitations. Our handling of scientific doctrines is controlled by the diffused metaphysical concepts of our epoch. Even so, we are continually led into errors of expectation. Also, whenever some

new mode of observational experience is obtained the old doctrines crumble into a fog of inaccuracies. (p. 154)

Disparaging speculation involves denial of this, claiming that there is an indubitable ground or method underpinning knowledge that is beyond questioning. Speculation in its broadest sense brings into question all claims to certainty and is radically opposed to such dogmatism, including dogmatic skepticism.

That is, for the defenders of speculative philosophy, speculation is not separate from other realms of discourse that can achieve certainty, let alone an inferior discourse. All discourses are based on assumptions that are questionable. Speculative thinking acknowledges this explicitly, not only about itself but also about other discourses and activities. Speculative philosophy is not self-contained but exists through constantly engaging with other discourses, activities, and forms of life and brings the assumptions of these into question, revealing the possibility of replacing them. Particular issues or entities can be focused on, but by the very nature of this must lead to questioning of the boundaries defining these issues or entities. Questioning inevitably leads to the crossing of disciplinary boundaries and then to philosophy in its original sense as love of wisdom, associated with the quest for a comprehensive understanding of the cosmos in all its complexity and our place within it. Beyond questioning, speculative philosophy proposes new ways of conceiving the world, providing new insights, opening up new avenues of inquiry, new research programs, new projects for action, and the possibility of new forms of life.

The difficulty in characterizing what is involved in such speculation is evident not only in the differences between different philosophers but from Whitehead's claim (1929, p. 51) that "speculative Reason is in its essence untrammelled by method. Its function is to pierce into the general reasons beyond limited reasons, to understand all methods as coordinated in a nature of things only to be grasped by transcending all method." This can never be finally achieved. As Whitehead continued, "This infinite ideal is never to be attained by the bounded intelligence of mankind." Speculation is best

characterized through its history, although it has to be recognized that any portrayal of it is itself provisional with the potential to be transcended. However, as noted with reference to Hegel, the revived defense of speculation in Germany following Kant was inextricably linked with the notion of dialectics, and it is in relation to dialectics that it is best characterized. Dialectics itself has been characterized in different ways, however. This is not a problem since thinking dialectically involves taking anywhere as a starting point and through critique and considering then developing alternatives, moving to more adequate characterizations of that which is being investigated. For Plato, dialectics was the art of conversation in pure thinking. German speculative philosophers built on Kant's use of the term "dialectics" but rejected his characterization of dialectical arguments as sterile, never able to reach conclusions. While incorporating Kant's insights on imagination and concepts, they used Plato's notion of dialectics to reconceive it as creative.

Fichte, and following him, Hegel, Schleiermacher, and Schelling regarded their work as speculative because along with experience of sensible objects and the concepts required to cognize them, they gave a place to a third kind of experience – experience of the development of cognition and then appreciating the adequacy or otherwise of concepts used to interpret experience. Fichte embraced Kant's argument that there is a synthetic component to all our experience and judgments, involving imagination and construction, but went beyond Kant to argue that we can explain concepts as emerging through the organism's practical engagement in the world and that synthesis also makes possible speculative knowledge, knowledge of how old concepts could be brought into question and new concepts and conceptual frameworks elaborated to replace these. In characterizing this process, "synthesis" was used by Fichte to reformulate dialectics as a dialectical synthetic method. It involves revealing contradiction or vicious circularities in previously derived sets of propositions and then seeking out some new higher principle that allows one to avoid the contradiction or circularity and is therefore declared "necessary." There can be no algorithm

for solving such problems. Every such problem must be dealt with in its own terms, each requiring a fresh exercise in creative problem-solving. This is not conceptual analysis, logical inference, or syllogistic reasoning, nor is it empirical observation, but is thoroughly synthetic. It cannot be derived from the problematic set of concepts it resolves but is a product of imaginative thinking.

Hegel's reformulation of this dialectic involves three steps: taking a view, belief, concept, or category as fixed and then reflecting on this to reveal what is implicit within it but also to reveal its abstractness and one-sidedness and one or more contradictions. This is followed by a speculative step of positive reason in which a higher stage is reached which embraces earlier beliefs, concepts, or categories to achieve a more concrete, because less one-sided perspective. However, Hegel only gave an attenuated place to imaginative thinking. The later work in *Logic* was criticized by Schelling for geometrizing the dialectic, failing to acknowledge the creativity and openness of dialectics which, Schelling claimed, can never be completed.

Building on Plato's, Hegel's, and Fichte's notions of dialectics, Schelling went on to challenge Newtonian science to align science with history and art. Thought, including thought associated with practical engagement in the world, is inherently synthetic, Schelling argued, and begins with genuine opposition either between thought and something opposing it or other factors within thought. This necessitates a new synthetic moment that can be treated as a product or factor in the next level of development. Building on Kant's and Fichte's ascription of a central place to imagination in such synthesis, Schelling developed Kant's concept of construction and extended Fichte's genetic approach from the development of cognition to the development of the whole of nature. He characterized "intellectual intuition" as a form of knowledge gained through a reflective and imaginative experimentation and construction by the productive imagination of the sequence of forms produced by the procreative causality of what is unconditioned (the "Absolute"). Referring to this dialectic as the "standpoint of production" in contrast to the Kantian "standpoint of

reflection," Schelling sought to show not only the social conditions for objective knowledge (as with Hegel) but the nature of the world that enables it to be known objectively and explained while at the same time producing life and subjects that can achieve knowledge of it and of themselves. In doing so he gave a place to will as well as constructive imagination in the production of truth. This in essence is the whole project of *Naturphilosophie*, or speculative naturalism.

This work on speculation and dialectics was enormously influential, but later developments of these ideas were fragmented and often made no mention of speculation or dialectics. Schleiermacher, a contemporary of Hegel and Schelling and strongly influenced by Schelling, lectured on dialectics and intended to produce a work on this as his *magnum opus*, but died before he could write it. He is now known principally for having inspired the development of hermeneutics. While work on hermeneutics should be seen as advancing our understanding of dialectics and speculation, especially in the case of Paul Ricoeur, these terms were not used. Karl Marx and the Marxists also developed dialectics. However, Marx's dialectics influenced by both Hegel and Schelling was primarily critical, and Friedrich Engels' dialectics formulated as three laws was fundamentally undialectical. Both tended to extoll praxis as superior to speculative thinking. The identification of dialectics with Marxism had the unfortunate consequence that the term "dialectics" was dropped from the vocabulary of philosophers who did not want to be identified with Marxism, just as the identification of speculative philosophy with Idealism led other philosophers to avoid the term "speculation." Speculative dialectics had its most significant impact on work in the philosophy of science, and here that it was best defended, but it was not identified as such.

Speculation and the Philosophy of Science

While major scientists continued the Schellingian tradition of speculative naturalism, freeing themselves from the assumptions of Newtonian

science, reflections on science itself came to be dominated by the development of symbolic logic, that is, logic incorporating algebraic methods of reasoning developed in mathematics. This culminated in the development of logical empiricism and logical positivism emphasizing the importance of deductive logic, giving some place to inductive logic and no place to speculation. However, some of the most important logicians rebelled against this and did defend speculation, most importantly, C.S. Peirce and Alfred North Whitehead.

Influenced by Kant, Hegel, and Schelling and a scientist himself, Peirce as a logician argued that along with deduction and induction, there is also “abduction.” This is another name for speculative reasoning, while Peirce’s characterization of the circular relationship between these three forms of reasoning is really a further development of work in dialectics. For Peirce, abduction is the most important form of thinking, exemplified by Kepler’s explaining the observation of the observed positions of planets by postulating elliptical orbits. He was interested not only in particular scientific theories and defended metaphysical speculation, arguing that without reflection on metaphysics scientists are dominated by crude, unexamined forms of metaphysics. Abductive thinking is “ampliative,” that is, creative. Although not fully developing the idea, Peirce held such thinking to be metaphorical. He noted (1998, p. 392): “Metaphysics has been said contemptuously to be a fabric of metaphors. But not only metaphysics, but logical . . . concepts need to be clothed in such garments. For a pure idea without metaphor . . . is an onion without a peel.” Deduction as “necessary reasoning” has a place in working out the implications of ideas postulated through abduction, and observations are made on the basis of questions posed in terms of such ideas.

It was Whitehead, however, who focused explicitly on defending speculative philosophy. His contribution to understanding speculation was obscured by his claim that it has no method. Seen against the background of the history of speculative dialectics, however, it becomes apparent that Whitehead was part of this tradition and

making a number of important contributions to it. When it came to proposing new ideas or theories, he claimed a method of descriptive generalization, meaning “the utilization of specific notions, applying to a restricted group of facts, for the divination of the generic notions which apply to all facts” (Whitehead 1978, p. 5). Although he seldom used the term, he also was invoking the use of metaphors. He showed what is involved in elaborating and extending such theories by committing oneself to them, striving to show how they can be applied first in one case and then in all other cases. He observed the difficulty of avoiding blind spots in any speculative metaphysical scheme and argued that it is only through having rival schemes that the limitations of each could be revealed.

While the philosophies of Peirce and Whitehead were marginalized by logical empiricism, phenomenology, and ordinary language philosophy, from the 1950s onwards, their ideas were resurrected by historically oriented philosophers of science. Norwood Russell Hanson revived Peirce’s work on abduction in his work on patterns of discovery. Thomas Kuhn was strongly influenced by both Hanson and the historian of science, James Conant, who in turn had been strongly influenced by Whitehead. Later philosophers of science extended and refined their work. Most importantly, they examined the role of metaphors in science. Mary Hesse and Rom Harré were involved in this, but the most profound insights on metaphors came from Mark Johnson and George Lakoff. Johnson defined his own work as a development of Kant’s philosophy; however, his doctoral thesis was supervised by Ricoeur, and in transcending Kant’s philosophy, his work mirrored the earlier transition from Kantian critical philosophy to speculative dialectics. Lakoff then showed how mathematics itself is based on the elaboration of metaphors. Johnson and Lakoff together showed that language is largely composed of metaphors and metonyms, evidencing the speculative element in all our thinking and experiencing. Despite not defining this as the study of dialectics or speculation, work on metaphor has greatly advanced our understanding of speculation and its significance.

Summary: Speculation and the Possible

Freed by the proponents of speculative philosophy and post-positivist philosophy of science from the distorting claims of scientism, we can now recover the original meaning of speculation as reflective observation, enriched by the work of these philosophers. Peirce's notion of abduction provides the most useful starting point. This is the dimension of reasoning left out by logical empiricists in their characterization of valid reasoning, and from Peirce's perspective, it is the most important part of reasoning. Abduction is not simply a matter of deductive necessity nor of making provisional extrapolations on the basis of observed regularities, nor a combination of them, while deduction and induction presuppose previous abductive inferences. These are in the form of metaphors, beginning with metaphors that have congealed into the background, habitual assumptions as dead metaphors, or new metaphors. Speculative enquiry begins with questioning these previously taken for granted ways of perceiving and interpreting experience, making explicit the metaphors underlying them and making it possible to replace them. One of the most important challenges is to ask the right questions. The next step is to explore alternative ways of interpreting or conceiving that which is being questioned, and it is here that more creative thought is required. It is here that the deployment, development, and utilizing of new metaphors to overcome contradictions, inconsistencies, paradoxes, blind spots, and one-sidedness in past beliefs and interpretations of experience becomes important. Then comes the difficult process of articulating these metaphors into coherent frameworks of concepts and elucidating experience through them. To avoid blind spots, it is necessary to entertain other possible ways of making sense of that which is being examined and choose between them. This is a dialectical process which also grants a place to deduction and induction, but always understood in relation to abduction. No phase of this is easy or straightforward, and there is no ultimate finality in inquiry. Speculative thinking exposes one-sided thinking and leads beyond particular situations and problems and ultimately brings into question

the deepest assumptions of science, philosophy, and civilization and constructs of alternatives in the unending quest for insight and a coherent, comprehensive understanding of the world.

Acknowledging speculation in this sense supports Vico's claim that humanity is largely self-creating. Through speculation, not only are new possibilities for research opened up as taken for granted assumptions are brought into question and radically new concepts and ways of thinking developed, but new possibilities for society, civilization, and humanity are created. We can reconceive our conceptions of ourselves and our relations to each other and to other life-forms, not only theoretically but practically, envisaging and thereby creating new possibilities for the future, transforming the way we live, the way we organize, and how we engage with the rest of nature. As Mikhail Epstein (2012, p. 7) argued, humans create themselves by creating "new images, signs and concepts of themselves . . . humans do not so much discover something in the world of objects as build their very subjectivity by way of self-description and self-projection." Speculation frees us from the assumption that we are condemned by human nature to continue on our current paths, no matter how disastrous the consequences. Speculation creates new possibilities.

Speculative Research

Mike Michael¹ and Alex Wilkie²

¹Department of Sociology, Philosophy and Anthropology, University of Exeter, Exeter, UK

²Department of Design, Goldsmiths, University of London, London, UK

Abstract

This entry begins by distinguishing speculative research from the broader cultural and academic meanings of “speculation.” The present “constructivist” approach to speculative research places emphasis on the ways in which the research question, the researcher, the researched and research device are actively involved in a process of becoming-with one another. This is explored through the notion of the “research event” into which a multiplicity of divergent elements (micro and the macro, the social and the material, the cognitive and

the affective, and the human and the non-human) enters. In combining, they also “become-with” one other thereby opening the potentialities of the research event, including the possibility that it is no longer “about” research. Speculative research concerns enabling a sensibility attuned to this process of co-becoming. The entry suggests that a sensitivity to, and a taking seriously of, the “idiot” (i.e., that which does not make sense in the context of the research event as typically understood) facilitates this openness to the possibilities of the research event. More proactively, speculative researchers can also introduce idiocy into research events as a way of prompting participants to explore potential ways of reframing the research question, that is, of inventing new problems. The device of the “probe” (drawn from **design** practice) is used to illustrate this. It is further proposed that speculative research extends to the data analytic phase: introducing alternative materials (e.g., nonacademic artifacts) or traditions of engagement (e.g., **aesthetic**) can also enable “possibilistic” accounts.

Keywords

Speculation · Constructivism · Event · Research · Device · Idiot · Probe · Possible · Co-becoming

Introduction

Speculative research is a mode of empirical engagement that places emphasis upon the not-yet, the potential, the emergent, the **possible**, the co-becoming. Needless to say, these terms do not always map happily onto one another. For example, some authors would argue that the “**possible**” is emergent in the flow of a world of becoming, rather than provoked by methodological intervention; indeed, some would argue that it is not **possible** to operationalize the possible through a method; some authors would insist that at best it is only **possible** to become sensitive to a field of potentialities rather than specify particular possibilities. For present purposes, however, we

conceive speculative research in terms of the notion of the “research event” which is part of a world of becoming and thus might well emerge as something other than research. The obverse is that ostensibly non-research occasions may become “research” in the process of their eventuation. The point is that to talk about speculative research is not only to address the substantive issues inherent to research (e.g., energy demand reduction, science communication, biomedical innovation, etc.) but also to become open to different possibilities, the non-research and other-than-research possibilities immanent in a research event. The upshot of this formulation is that it is necessary to keep a fluid sensibility not only to the conduct of speculative research but also to what speculative research might actually entail.

In what follows, there is an initial outline of various approaches to speculative research. This is followed by an extended consideration of a particular approach to the speculative, including an explication of the relevant philosophical and practical underpinnings not least those that relate to the concept of the event. Following this, examples are provided of a number of conceptual and empirical tools. Particular attention is paid to the role of the philosophical figure, the “idiot” and how this manifests in a particular speculative tool the “cultural probe” (or “probe,” for short). This focus serves not only as a means of setting out key parameters of operationalizing speculative research but also a means to addressing and differentiating a variety of forms speculative research. Throughout, there is an insistence that there is nothing straightforward about these speculative “operationalizations” of the **possible**; they can, through a range of processes, undermine the **possible** and reinforce the probable.

Researching and Speculating

Recently, the notion of **speculation** has attracted renewed attention by social scientists and cultural theorists interested in understanding, explaining and theorizing process, novelty, becoming and individuation as immanent features of sociality. Although the term is typically associated with

risk, irresponsibility, or opportunistic endeavors (arguably, the precise opposite of sober empirical research) or an outmoded branch of philosophy interested in the exercise of pure imagination, **speculation** has gained renewed value as a way to critically explore possibilities and futures in contemporary societies marked by calculative logics and developments in science and technology. In so doing, and crucially, the version of **speculation** that we present here seeks to avoid the reduction of the speculative to a cognitive capacity or economic activity (Uncertain Commons 2013).

Clearly, then, the question of **speculation** raises issues related to sociotechnical futures and temporality which have been a longstanding preoccupation of social analysis. Social research, for instance, has a rich tradition in examining the discursive practices and rationalities by which societal futures are accomplished (or not) and managed, perhaps most recognizably through the identification and management of risk in “reflexive modernity” (Beck 1992) as well as the construction of hopes and expectations associated with new technoscientific developments (e.g., Brown et al. 2000). The move to the speculative, however, and as scholars interested in empirical **speculation** have argued (e.g., Savransky et al. 2017; Wilkie 2017), demands a shift in register from analyzing the manifestation, management, and contestation of probabilistic futures – how typically “rational” actors envision, model, predict, coordinate, and, in turn, configure the future in the present – to the construction of adequate concepts and devices for exploring **possible** latent futures.

Arguably, two distinct realist approaches have recently emerged as ways to understand, explain and theorize process, novelty, becoming and individuation, which seemingly share similar concerns but in actuality differ quite markedly. In brief, the first, entitled “Speculative Realism,” is the philosophical preoccupation with realism and ontology independent of thought and language (for an introduction, see Bryant et al. 2011). The various approaches associated with speculative realism have been inspired by Quentin Meillassoux’s (2008) “correlationist” argument

where thinking and being are viewed as indivisible, thus rendering knowledge of an independent ontological reality beyond thought and language a question of **speculation**. The second, which has occasioned considerable interest for social and cultural researchers interested in empirical **speculation** (see, for instance, the volume Wilkie et al. 2017), can be understood as a **constructivist** approach and draws on the work of A.N. **Whitehead**, Gilles Deleuze, and Isabelle Stengers. Here, speculative thought is practiced as a means for designing and constructing adequate concepts and “devices” that “actively relate knowledge production to the question it tries to answer” (Stengers 2008, p. 92), a process in which it is assumed that the research question, the researcher, the researched and research device are actively involved in a process of becoming-with one another. What counts as “real” in such research practices is a question of the strength and robustness of more-than-human distributions (constructions), and not simply the meanings, discourse or imaginings of persons. This, then, relates knowledge production to the question it tries to answer and the means by which this is achieved, evoking **Whitehead**’s ontological principle that states “there is nothing which floats into the world from nowhere” (**Whitehead** 1978 [1929], p. 244), including the researcher, the researched, and the instruments of research.

This **constructivist** approach to speculative method (see also Wilkie et al. 2015) can also be understood to follow Bruno Latour’s (2004) contradistinction between the “critical” and the **constructivist**. Here, and for Latour, to engage in **constructivist** analysis involves the production of more adequate explanations, rather than deflating or debunking the explanations and claims of others. In this view, debunking can also be understood as associated with the impetus to provide access to truth hidden by explanation or abstraction. By contrast, **constructivism** aims to strengthen the production of knowledge by actively acknowledging the practices and techniques by which knowledge, and indeed abstractions, come into being and in so doing concerns itself with the fabrication of concepts and

explanations as well as the devices and technologies that partake in the process of research – which, in the next section, we characterize as the “research event.” This, then, leads scholars interested in **speculation**, process, and change to engage in so-called inventive methods (Lury and Wakeford 2012; Marres et al. 2018) and the question of devising instruments and devices that relate to the staging and animation of the question or topic at hand (e.g., Guggenheim 2017). As Wilkie (2017, p. 348) argues, this demands a move from device-centered analysis (Marres 2012, p. 81) to a device-centered method and the devising of associated concepts and more adequate modes of abstraction (**Whitehead** 1997 [1925], p. 59) that this necessarily entails. If the speculative tools for philosophy are concepts that act as “lures” to vectorize thought (Stengers 2008, p. 97), then the instruments and techniques of empirical social research can be understood as part of a speculative toolkit. In this respect, such empirical “methods” act as “lures” for the **possible**. However, they demand a practico-theoretical care in their crafting and deployment not least because there is always a danger of retrenching the probable (de la Bellacasa 2017).

Research Event, Co-becoming, and the Possible

In the view adopted here, speculative research needs to begin with a version of the research event. This is because the event, as derived from the work of **Whitehead**, Deleuze, and Stengers, is marked by the multiplicity of divergent elements that enter into it. Accordingly, events are situated unities that entail heterogeneous elements – which **Whitehead** (1978 [1929]) names “prehensions” – that include both the micro and the macro, the social and the material, the cognitive and the affective, and the human and the nonhuman. These “concresece” or combine to produce a singular actual occasion or entity. Importantly, in the process of the concrecence of prehensions, those prehensions – the constitutive elements of the event – can, as Mariam Fraser (2010) argues,

“become-with” one other. This version of the event implies what Connolly (2011) calls “a world of becoming” in which as elements combine to produce events (which in turn combine to produce “subsequent” events), there is an unfolding of the world that can be unexpected or novel or, “possibilistic.”

In applying this model of the event to research, the social scientific “research event” becomes less a process in which, through standard methods, the researcher engages and documents the social world. Rather, it is an occasion in which the various elements that are involved in the research event – broadly, the researcher, the researched, and the research (devices, settings, objectives, etc.) – can mutually co-become. In the process, there is no easy way of “finding stuff out” for both “finding” and “stuff” might have shifted. Rather than seeking a solution to the research problem that originally underpinned the research, it is important to orient toward a different matter, namely: what has become newly interesting about the research event? In this sense, research becomes a case of asking better questions, or, as Fraser (2010) has framed it, of “inventive problem-making.” Put simply, the research event as articulated here implies that researchers need to be circumspect about looking for answers to preformulated research questions and should sensitize themselves to the co-becoming that occurs in the research event in order to derive more inventive problems. The corollary to this is that researchers are themselves entangled in the becoming-with of the research event, and, as such, they need speculatively to engage with – to practice what Connolly (2011) might call “exquisite sensitivity to the world of becoming” – how the research event unfolds toward the **possible** (even when it unfolds into something other than an identifiably “research” event). In the broadest sense, this perspective suggests a methodological sensibility that requires “an openly **constructivist** approach that affirms the **possible**...actively resists the plausible and the probable targeted by approaches that claim to be neutral.” Stengers (2010, p. 57).

Responding to the Idiotic in the Research Event

One way in which the researcher might respond to the novel or possibilistic unfolding of the research event is by becoming attuned to the idiotic during empirical engagement with participants. The “Idiot” is a philosophical figure whose behavior “does not make sense” within the assumed framework of the (research) event. The idiot thus “resists the consensual way in which the situation is presented in which emergencies mobilize thought or action” (Stengers 2005, p. 994). Its analytic usefulness lies in the fact that it remains indifferent to the researcher’s concerns and thus opens up the possibility of prompting the researcher to wonder whether “there is something more important” (2005, p. 994) going on in the research event which the researcher has yet to grasp. In other words, is the research event comprehensible in other ways – ways that might challenge the assumptions on which the research event rests?

One implication of this framing is that certain burdens are placed on the researcher. In particular, they must exercise care with respect to the idiot (and indeed the self), taking its ostensible waywardness seriously rather than neglecting, ignoring, or dismissing it (de la Bellacasa 2017). It is, after all, often difficult to identify the idiocy at work in a research event: school students’ collective proliferation of accounts reflects not the pre-existing range of accounts but a competitive game of collective creativity. Or, it is easy to see research failure and to self-derogate: an interviewee’s unwillingness to answer the research questions reflects not the incompetence of the interviewer but the enabling copresence of her companion animals (see Michael 2012). What such a careful sensibility toward idiocy does is enable **speculation** about the **possible** meaning of these events, to seek in them more interesting problems. Does the students’ playfulness suggest that the research event can be an occasion for testing the believability of accounts? Does the interviewee’s resistance indicate that the interaction of hybrids – combinations of humans and

nonhumans – might be more useful ways of thinking about the unfolding of interview research events?

In this section, the focus has been on carefully detecting the idiotic in the research, sensitizing the researcher to the ways in which the idiotic prompts new possibilities, and, in particular, more interesting problems. The idiotic is used here simply to indicate those actors or moments or behaviors that can be understood as not “making sense” within the framing of the event as a research event. On this score, the idiot is indicative of other ways that social scientists engage with the **possible** through “making the familiar unfamiliar” (Highmore 2002), “attunement” (Stewart 2011), “breaching” (Garfinkel 1967), or “idle walking” (De Certeau 1984).

However, it should not be forgotten that the researcher too might appear idiotic to participants in research events, not least when their questions, framing, or problems make little sense to the participants. This raises the interesting prospect that researchers can deliberately introduce idiocy as a part of a research strategy that potentially entails the novel unfolding of the research event in ways that engage the **possible** and are generative of more inventive problems. The above, however, also warrants a caution to resist anthropomorphizing the idiot, which for our purposes is a figuration of certain kinds of processes taking place in the (research) event.

Introducing Idiocy into the Research Event: The Probe

To introduce idiocy into the research event involves the staging of a mixture of the familiar and the unfamiliar. Firstly, the “idiotic device” or “idiotic moment” must be sufficiently unfamiliar (strange, opaque, playful, open) that the participants in a research event find themselves curious, intrigued, and, crucially, willing to engage with it. The idiot cannot be too unpredictable, otherworldly or threatening otherwise it will simply alienate participants, who will dismiss it, or ignore it (much as researchers might disregard participants who are “idiotic” – see above). Needless to

say, it might be the case that participants are themselves resistant to the strangeness and undecidability of the idiotic device, might have recourse to “conventional wisdom or power” as Connolly (2011, p. 159) has remarked.

So, what forms can these introduced idiots take? Here, the emphasis is placed on a particular sort of idiotic device, drawn from a speculative and critical traditions in **design**: this is the probe. In what follows, we consider and illustrate its broad characteristics.

Boehner et al. (2012) describe probes (shortened from the original term, “cultural probes” – Gaver et al. 2004) as designed to access “what might be.” Instead of pursuing accurate representations and generalizable findings, probes are focused on rather more partial, risky and idiosyncratic accounts that can be understood to serve as **speculations** on how the research event might unfold. They are usually comprised of objects and instructions that ask the participant to engage in an odd exercise. Often probes are collected together in a package that is sent to volunteers or distributed at research events. The following is a selection of probe tasks that Gaver and his collaborators have designed and distributed:

- A “Listening Glass” which is a standard drinking glass with instructions that ask the volunteer to press the glass against a wall so as to hear the unusual sounds produced by the house. A marker pen is also included so that the perceived noises and their meanings can be recorded directly onto the surface of glass.
- A customized disposable camera that includes instructions to the volunteer to photograph something observed from their kitchen window or to photograph the spiritual centre of their home.
- The “Telephone Jotter Pad” allows participants to add to doodles to it in response to the images or questions it incorporates, and while engaged in other activities (not least answering the telephone).
- Community maps where members of different constituencies interested in energy demand reduction were asked to produce a visualization of their “common community” using a

preprepared map projection with pens and a variety of specifically designed stickers that included depictions dinosaurs, spiders' webs, cups of tea, alien spacecraft, and the like.

- Participants were asked to write their guilty energy-use secrets or an obituary for a favorite appliance on a specifically designed pre-addressed and postage-paid letter or an obituary template, respectively.

By virtue of their oddness, playfulness, opaqueness, and so on, each of these probe exercises were designed to leave open the sorts of responses that were **possible**, to prompt their users to think otherwise, and, indeed, to trouble any presumed framing of the research event in which they (and the researchers) were involved. For instance, in the examples mentioned in last two bullet points, which were part of a large research program investigating the role of community on energy demand reduction (Boucher et al. 2018), part of the aim was to challenge the typical meanings of “community” that inform such research. Does constructing a collective community open up the possibility that “community” is at once fragmented, contested, competing in unexpected ways? How does admission of guilty energy usage situate the participant in relation to their energy demand community (which might be composed of many guilty energy usages)? Does writing an obituary for a favorite appliance imply that appliances are part of a community, and what does being a “part of” mean in this context?

In summary, the use of probes, because it renders the research event uncertain, opaque, playful, etc., serves as a means to prompting **speculation** among participants. This **speculation**, in turn, serves as a prompt for the researchers to open up their assumptions about what their research is about, and to facilitate their own **speculations** about the possibilities of what might count as an interesting research problem.

Now, the probe is just one technique by which the **possible** is prompted. Other researchers might craft a set of speculative objects or activities in collaboration with the participants themselves (e.g., Dantec and DiSalvo 2013) or might invite

participants to speculate on the **possible** by considering or contemplating (rather than practically engaging with) exhibited, more or less highly finished technological designs whose functions remain opaque or uncertain (e.g., Dunne and Raby 2013). Once again, having made these points, there are no guarantees that the probes (or other such objects) will work: designers and social scientists who use probes acknowledge that not everyone responds positively, or at all, to the tasks set in the probes.

Analyzing Idiotically: Speculating with Others' Speculations

The materials – the texts, images, recordings, etc. – that are returned from the probe exercises need not be treated in the usual social scientific ways. These “data” need not be studied and mined in order to discover common themes, or analyzed in order to identify patterns of meaning (such as opposing discourses, or an array of imaginaries, or a nexus of significations). Rather, the ethos of engagement with these can be more idiotic insofar as it seeks those elements that “make no sense”: images, juxtapositions, text, scribbles, murmurings that invite speculative researchers “... (to) slow down, so that (they) don't consider (themselves) authorized to believe they possess the meaning of what they know” (Stengers 2005, p. 995). In relation to the present formulation of the research event, the researcher is opening themselves up to co-becoming with these materials in novel ways. Put otherwise, the research needs to “bestow efficacy upon the murmurings of the idiot” (Stengers 2005, p. 1001) so that what counts in the research can be interrogated, revisited, or reinvented. It is important to note, however, that any “data,” whether derived through speculative research or through more traditional social scientific methods, can be subjected to this sort of speculative engagement (e.g., Stewart 2007).

This speculative engagement with data can involve several activities. For instance, data can be analyzed in terms of what appears especially unexpected or unusual. Or they can be situated in

relation to a range of other materials both academic and nonacademic (Highmore 2002). Regarding the former, inviting others into the analytic moment can yield unexpected readings, especially if they themselves have a peculiar, distinctive, or idiosyncratic perspective on the more or less relevant academic literature (what Billig 1988, called “scholarship”). With regard to the latter, links, juxtapositions, comparisons, etc. with texts and images drawn from a variety of media (such as magazines or newspapers, from the histories of **design** or art, etc.) can cast a different light on these data that open up the possibilities of attunement and engagement. It is also **possible** to treat such data “**aesthetically**” as a way of accessing the potential, or **possible** (see Michael et al. 2018). Specifically, as Massumi (2011) suggests, in the **aesthetic** encounter the experience of the artistic object or event can be fleeting, highly affective, emergent, and generally difficult to pin down. In the process, multiple possibilities can become available for how one grasps that object or event. The same can be said for the researcher’s engagement with their data: data become an opaque, shifting field of affects which enable the researcher to seek in them clues to the potential and the **possible**.

Spirit

► Spirituality

Spirituality

Erik Mansager
Webster University, Geneva, Switzerland

Abstract

This article imbeds the concept of spirituality within lived human experience, as a holistic rather than other-worldly phenomenon. It starts with a review of the history of the word “spiritual” that gave birth to a concept of “spiritual-ity.” The development of word and concept are

traced within their specifically Christian context and then viewed to see how they were experienced and explored as independent of this original religious mooring. Spirituality is then seen as an aspect of the world religions before investigating the notion that it can be considered, in part, the substance of the human capacity for making meaning. As a result, it is described both as the *transformative experience* the word was originally intended to convey and as an *academic discipline* whose aim is to study such experiences. The examples of academic studies were selected to illuminate the variety of fundamental human activities which comprise spirituality as defined below.

Keywords

Spirituality · Transformative experience ·
Meaning making · Self-transcendence

Synonyms

Inspiration; Integration; Mindfulness; Prayer;
Self-transcendence; Self-transformation; Spirit;
Striving; Ultimate value

Definition

Definitions for *spirituality* proliferate among scholarly disciplines – religious and theological as well as sociological, anthropological, and psychological. What Allport (1950), for example, identified as “religious sentiment” includes the “spiritual activity” of seeking ultimate meaning or ultimate value – whether concerned with theism or not. This “search for the sacred” (Pargament 1999) addresses a rudimentary riddle of human existence. While spirituality shares with these other disciplines the universal search for knowledge and meaning, it is distinguished from them by the *direction* in which it poses its questions (e.g., about the sources of transformative experiences) and the *area* from which it anticipates its answers (e.g., which discipline will provide understanding, Küng 1987/1988; Ricoeur 1976).

Examination of the meaning-making creativity of such deep human inquiry has discerned four characteristics of an individual's spiritual movement – each of which intertwines with facets of the possible:

1. The universal human activity of *striving* – a teleological movement that acknowledges “we live lives that are fundamentally oriented towards the future” (Glaveanu 2018, p. 524).
2. The effort made toward life *integration* – an interweaving of dimensions which “make sense of the past, present, and future, both individual and collective” (Glaveanu 2018, p. 523).
3. The pursuit of *self-transcendence* – which moves beyond integration “and, above all, transforms our experience of the actual” (Glaveanu 2018, p. 519).
4. The conceptualization of one's *ultimate value* – that which though subjective, cannot be surpassed given its embrace of infinite perspectives, in Glăveanu's (2015) parlance.

The interconnection of these characteristics takes account of more succinct descriptions such as “striving to make meaning” (Emmons 2005) as well as the humanistic approach of “developing one's self to one's full potential” (Mansager and Bluvshstein 2017). Spirituality scholar, Sandra Schneiders (1986), originally took the terms from her broad consultation among male and female, interdisciplinary scholars who represented numerous Christian denominations from Europe, North, and South America. The consensus definition she employed follows:

[T]he experience of consciously striving to integrate one's life in terms not of isolation and self-absorption, but of self-transcendence toward the ultimate value one perceives. (p. 266)

Herein, the four salient features intertwine to characterize spirituality in a broad number of human sciences (e.g., sociology, linguistics, history, feminism, ecology, business management, etc.) which focus on its many possible human expressions. Still, the terms striving, integration, transcendence, and ultimate value are not captive to any one academic field. When a commensurate use of

the terms is agreed upon among the many invested disciplines devoted to study spirituality, a robust, developmental understanding of spirituality emerges.

Introduction

Fitting the spirit of Palgrave's *Encyclopedia of the Possible*, this article is not a straightforward academic presentation on the topic. The author presents a broad and somewhat provocative look at what spirituality could *possibly* mean in the run of everyday life and intends to look at spiritual movement as a *human* phenomenon. What “possibility” means in this arena is that the wonders and inspiration typically associated with spirituality can be viewed as part and parcel of the human being's fundamental make-up! The desire to grow beyond or transcend oneself, the search for deeper meaning, or the urgency to live a full and meaningful life entails accessing wholly human abilities or potentials (e.g., Collins 2010; King 2013). Whether these abilities are evolutionarily developed (e.g., Groff and Marx Hubbard 2014), are “god-given” to the human being (e.g., Wilt et al. 2019), are generated from past-experiences in this life (e.g., Illman 2012), or are felt as if they come from several prior lives (e.g., Bender 2007), the intentionality and anticipation of spirituality still activates the here-and-now, flesh-and-blood individual. The spiritual proclivity resides in the human heart and mind.

This much we can experience.

Our holistic world is marvelously intertwined and there need be no final agreement on what power or entity – if any – generates our deeper inward movements – inside or outside us. Speculation, study, and conclusion on such matters will be addressed in collateral articles within this *Encyclopedia of the Possible*. It will be enough for this article to lay out simply but clearly – in two movements – the opportunity and challenge that spirituality has presented since its initial conceptualization in history. The first movement is one of personal *experience* (“History and Development of Spirituality”) which describes how spirituality developed after its inception. The

second movement is one of *exploration* (“Interfacing with Other Disciplines”) which lays out how scholars have grappled with spirituality and formulated their craft to do so. In terms of the possible, the author’s structure reflects Thrash and Elliot’s (2004) finding that “inspiration” – understood here as more than etymologically related to spirituality – has the relatively passive characteristic of *being inspired by*, which is addressed in the first movement, as well as the more active characteristic of *being inspired to*, which is addressed in the second movement). Throughout the article, the author interweaves representative examples of the transformative experiences as well as examples from spirituality scholars to illustrate the richness of the experience and the scholars’ endeavors. This won’t exhaust the matter, but it may go a good distance in the direction of helping the reader understand the long road of human interest in spiritual movement.

History and Development of Spirituality

First Millennium of the Common Era

Unlike religion itself, spirituality was not *originally* conceived to give expression to the most profound human experiences – even though it has come to express and to study those experiences. According to spirituality scholar, Sandra Schneiders (2005), the individual that coined the term “spiritual” was most likely Saul of Tarsus. He is better known by the name, Paul, which he took after a self-transcendent experience which left him adhering to the very beliefs of the nascent Christian community he was trying to eradicate from his Jewish homeland.

The concept of “spirit” (*pneuma*) was familiar in sacred and profane literature during his lifetime. Still, conceptualizing the word as an adjective, used in order to modify the understanding about and describe the experience of an individual, was altogether new at the dawn of the Common Era. In his newfound faith, Paul felt compelled to describe how he personally experienced – and how others seemed to be influenced by – the “Holy Spirit” of the god he newly understood as Judeo-Christian and his “resurrected

son,” Jesus. To distinguish his former Jewish associates and the few nonbelievers in his world, from the nascent Christian, posttransformation experience, Paul considered the faith filled Christian to be a “spiritual person” (*pneumatikos anthropos*); contrasted with the wholly “natural person” (*psychikos anthropos*) who was not so inspired (1 Corinthians 2:14–15).

The legacy which Judaism lent to current spirituality must not be overlooked, of course. Any history of the topic (the Seabury *History of Christian Spirituality* is followed here) acknowledges the Torah, Jewish liturgy, piety, the *Berakah* (blessing-thanks-giving) and especially Jewish mysticism as precedent and integral to Christian spirituality and the phenomenon of Christianity itself: Jesus (Yeshua) being embraced as the Messiah/Christ of the oppressed. The “*change of heart*” (*metanoia*) which Paul experienced and that allowed soldiers, judges, tax-collectors – whether remaining in-position or abandoning their position – to engage others in an absolutely different manner, was attributed to an “acceptance *into one’s heart*” of the spirit of god that Jesus proclaimed. This was the original understanding of spirituality. The constituent characteristics of spirituality as defined above – *striving* toward an imagined, newly possible completion, *integration* of one’s livelihood with one’s faith life, *transcendence* of one’s prior engagement in life and thus opening to the even-now-but-not-yet (Küng 1978/1980) and *ultimate value* the “Spirit of God,” “the Spirit of Christ” – can already be discerned here.

Throughout Paul’s lifetime, during the formation of the primitive Christian church, he promoted the importance of the “spiritual person” and described frequently how such transformed people could be identified. That is, they actively expressed “charity, joy, peace, patience, kindness, goodness, fidelity, gentleness, self-control” (e.g., Galatians 5: 22). These are the expressions which imitate a “divine love” (*agape*). This type of love was understood as an action-oriented caring which Jesus was believed to reflect from his “heavenly Father.” It was simultaneously what those *inspired by* the “Spirit of Christ” intended to emulate among one another.

The expression of “self-control,” which Paul includes in his list of spiritual characteristics above, is developed elsewhere in his writings into a more comprehensive asceticism which folds back into understanding the puzzling death endured by his “Lord, Jesus”: a criminal’s death. Jesus’ repugnant death by crucifixion was re-interpreted by Paul as the “cross of glory” – the divine expression of *agape* which led to the “salvation” of humanity. Paul’s having been *inspired* to develop an ascetic approach to life is mentioned here as being at the root of Christian spirituality and of Christian identity. It was by immersing themselves in such a spiritual lifestyle that Christians were able to endure and embrace so “wholeheartedly” the terrors of martyrdom during the early centuries of Christianity’s development. Thus, ascetics and martyrdom became identifying features of early Christianity. At the core of the ascetic spirituality lay “fasting and almsgiving” – wherein depriving oneself, assisted the Christian in being free from material *want* so that one could subsequently provide for the material *needs* of the poor (Bouyer 1960/1982a, p. 530).

Early in the fourth century, Roman emperor, Constantine ended religious oppression throughout the Empire, with the result of ending the hostility aimed at Christians. As persecution and martyrdom had become a defining aspect of the milieu in which Christianity had thrived, Christians subsequently needed to reassess their identity in the absence of persecution and martyrdom. Cessation of the persecution was considered a Christian triumph when Constantine himself converted to the soon-to-be-established religion. Still, *agape* and asceticism had gone hand-in-hand until that time. With its view of embracing poverty as Jesus had – ascetic monastic practices (some, notably severe) – developed symbolically to take the place of martyrdom.

Whatever one makes of the exaggerations and abuses of ascetic expressions of spirituality, they intended to focus on living in accord with “the Spirit of Christ,” “the Spirit of God” which Paul had so indelibly impressed on the Christian community. He did so by his preaching and writing, and, like the original disciples of Jesus and the later “Fathers,” he did so by practicing

rudimentary rituals such as baptism (with its symbolic dying into water and rising up in “new life”) and a liturgy of thanksgiving (*eucharist*). This shared meal became a frequent occurrence which assured the community’s persistent recollection (*anamnesis*) of Jesus “death and resurrection” legacy and offered the opportunity for regular demonstration of the “divine love” shared among the believing community. The meal setting included readings from Jewish scriptures – those which shed light on Jesus’ life and mission – along with letters from “the Fathers” – and “Mothers” if current research bears out the re-attribution of some scriptural authorship to female leaders in the early Christian community (Schüssler-Fiorenza 1984/1994).

After Constantine’s acceptance of Christianity, the religion and its spiritual expression spread beyond the Roman western world and came with him east to his new capital city, modern Istanbul then known as Byzantium (thus Byzantine empire). Later named in Constantine’s honor, Constantinople, this Greek-oriented empire came to interface and later clash directly with the newer religion from the middle east, Islam, during the seventh and eighth centuries. The Christian spiritual life of integration and self-transcendence was formed around two primary poles in the Byzantine world: the liturgy and the development of iconography – sacred art depicting “the Christ factor” (Bouyer 1982b, p. 549) as ultimate value.

All this is shared to present the externally consistent conception of an active spirituality practiced within the Christian context until the late middle ages – the eleventh century: Christian believers living lives of love expressed in gratitude to their god while embracing asceticism so they could be mindful of the needs of others and actually helpful to the needy. These threads were retained throughout the development of Christian spirituality during the first millennium.

Second Millennium of the Common Era

This stable, multifaceted expression lasted until the rise of Christian theological schools (e.g., primarily the Dominicans but also Franciscans), after which it took on new characteristics. In the first centuries of the second millennium,

scholastics made use of a developing command of philosophy to define more precisely “sound doctrine” (*orthodoxia*). This university, or school-based understanding, intended to “fit the facts of spiritual experience into its scholastic theory” (Leclercq et al. 1961/1982, p. 506). For example, it was within the philosophical milieu of the twelfth century that Paul’s first century countering of “the natural” to “the spiritual” person took on an added rational dimension. Rather than solely emphasizing “life in the Spirit,” monastic and philosophical developments so narrowed the concept that spirituality was promoted as the *positive* opposite of *negative* somatic, bodily experiences. In time, the material world was opposed by the spiritually minded, reform-oriented poverty movements of medieval Christianity – e.g., Waldenses and Cathars. For them, “spirituality” over against “materiality” was expressed by valuing the sanctity of the individual separate from a respect for the hierarchy and sacraments (Bouyer 1982b, p. 264). This new opposition earned the wrath of the established church leadership. Thus, the once “persecuted church” became the “persecuting church” of the thirteenth century. Persecutions against “heretics” were the inevitable outcome, even while the intentionally impoverished lifestyle persisted under the influence of a more “orthodox” Franciscan spirituality. At the time when church authority intermingled with secular authority in defeating the “heretics,” the concept of spirituality took on yet another meaning: differentiating the eternal from the temporal, legalistic order. From that point, spiritual life was conceived as more salutary than the material life. It could be distinguished from secular life and was conceived as an interior life of perfection. This involved “methodical systematic meditation, and active devotion to Christ in his mysteries” (Vandenbroucke 1961/1982, p. 457).

These later configurations of spirituality and the spiritual life, especially the legalistic aspects, seem to have dominated the next two centuries without displacing the core. Love, thanksgiving, and asceticism – the Paulinian fundamentals of spiritual life all firmly fixed in Christian scripture – were at the foundation of such fifteenth-century spiritual classics as *The Imitation of Christ*

(Thomas à Kempis 1380–1471). Thus, individual spiritual activity gained prominence by attending to the Christian scripture. The modern or “new devotion” (Geert Groote 1340–1384) which *The Imitation* championed, emphasized the search for inner peace: simplicity along with contemplation of Jesus’ death – with the aim of discerning the implications for one’s own death. Devotion gained prominence among initial Catholic reform movements as well as the official protesting “Reformers” of the sixteenth and seventeenth centuries (e.g., Calvin 1409–1564, Luther 1483–1564, Melanchthon 1497–1560, Zwingli 1484–1531), while the term spirituality took on different undertones among both Catholics and Protestants. The reformers reasserted that “justification” or “salvation” was won by adhering to the Christian faith found in its scripture. To varying degrees, Protestant attention to more outward signs of “election” became contrasted with spiritual activities and a Catholic turn inward which continued to reference the “interior life” of the believer.

By the eighteenth century, not exclusively among Catholics, the interiority of one’s faith life had been well-established along with a more individualized notion of “internal perfection.” Spirituality represented a promotion of “more than” the everyday living of one’s faith which Paul had promoted. The “spiritually devoted” intended to live exemplary lives of moral and contemplative perfection and as a result, the devout sought out guides to show the way. “Spiritual direction” became an initiative of sorts and in both the nineteenth and twentieth centuries which promoted this individual life of perfection as synonymous with the concept of spirituality.

From the eighteenth to the dawn of the twentieth century, spirituality became firmly set as “internal perfection.” This spiritual outlook seemed much affected by the cataclysm of dual World Wars in the first half of the twentieth century. These wars, waged primarily among Christian nations, resulted in a minimum of 76 million deaths. This slaughter, the likes of which the world had not experienced, spawned peace efforts that provided an opening among the Christian churches toward reconciling with one another. The peace effort seemed to act as a catalyst for

the deep soul searching that ensued, allowing the Christian churches to find a model of reunification. After the failed example of the League of Nations (1920), which was championed by the psychologically racially conflicted 28th US President (Yellin 2013), the churches in imitation of the United Nations (est. 1945), found its model and established the World Council of Churches (WCC) in 1948. This remarkable year brought forward not only the WCC, but also an opening toward the other world religions. After the horror of the Holocaust, the recognition of Israel (est. 1948) as a modern Jewish nation brought new awareness to that ancient faith; simultaneously Gandhi's (1869–1948) development of nonviolent protest brought attention to Hinduism and Islam. This dialogic confluence has seen rapid growth in awareness about how spiritual practices also characterize non-Christian religions.

Along with the political and religious developments that occurred during the twentieth century, the development of a “new psychology” early in the last century, lent itself to therapeutic intervention and the healing of the human person. The nascent psychotherapy movement directly impacted the “spiritual direction” initiative. Freud, Adler, and Jung – the “triple star” of the new psychology (Ellenberger 1970) – all interfaced with spiritual direction of their era: Freud (Meng and Freud 1964) by way of Pfister, Adler (1964/1933) by way of Jahn, and Jung (1970) who included an esoteric approach to psychotherapy.

Pastors such as Oscar Pfister and Ernst Jahn began incorporating psychological practice and theory into their “care of souls.” Eventually the “pastoral counseling” movement became an instrument for spiritual development and by mid-twentieth century spirituality had been embraced by a “third force” or humanistic psychology which proposed an inherent goodness in humanity along with the possibility in need of development: a “fully functional individual” (Maslow 1971). Perhaps primarily due to Jung's arcane methodologies, nonreligious examples of transformation became an object of psychological inquiry. Such openness acknowledged and prepared the way for

profoundly humane concerns to come into focus as expressions of self-transcendent experience – the health of the environment, equality among the sexes and sexual orientations, feminism per se, animal care, and the like. Soon enough, a “fourth force,” transpersonal or spiritual psychology (Ferrer 2001) developed. Psychology became especially juxtaposed with spirituality in the rise of a “New Age Spirituality” in the late twentieth century; devoted to “experiences in which one's sense of identity or self extends beyond (*trans*) the individual or personal to encompass wider aspects of humankind, life, psyche or cosmos” (Walsh and Vaughan 1993).

Such is the history of the development of self-transcending phenomena of spirituality. In Craft's (2015) words, what started as “possibility thinking” – a Christian description of a personal life changing experience – has since become recognized as a basic human possibility: a striving to integrate oneself in a transcending manner toward one's ultimate value.

Spirituality Interfacing with Other Disciplines

We are two millennia away from Paul's original conceptualizing about the “spiritual person.” Still, his development of spiritual life as embracing love, gratitude, and a level of poverty manifest in today's actualizing and transpersonal approaches to daily life. From mindfulness-based stress reduction (Kabat-Zinn 2013) aimed at restoring inner equilibrium to chronic-pain patients to the transformational psychedelic Ayahuasca ceremonies of South America and increasingly of Europe, which aim to discover one's inner self (Narby 1999), the path of understanding one's “inner life” remains a vibrant one. So, here at the end of a brief historical review, perhaps it is not too difficult to recognize that Schneiders' (1986) constituent aspects of spirituality are still operative in what is considered spirituality today:

- While physical and psychological “drives” are considered causal phenomena (etiology)

bringing about results after their occurrence, today such drives are contrasted with *striving*, or forward-planning, goal-oriented movement (teleology). It is striving that is emphasized by contemporary psychologists who identify a growing goals revolution in a postmodern world (e.g., Emmons 1999 following Adler 1931).

- *Integrating* one's life recalls "systems theory" found in several disciplines from anthropology, through political science and sociology, to zoology. It also suggests the importance of differing perspectives (cf., Glaveanu 2015) as well as the psychological concept of individuation (Edward et al. 1992).
- *Self-transcendence* is popular again partly due to transpersonal movements of our day. Other established disciplines such as humanistic psychology, existential philosophy (Frankl 1946/1984) also understand "going beyond" one's self-understanding does not need to be a transpersonal experience (Anderson 1991). Self-transcendence is considered a positive mental health characteristic which prepares one to contribute more effectively in everyday life (Ansbacher 1992).
- *Ultimate value* is understood as one's subjective evaluation about that which organizes action toward one's personal goals. Peoples' lives move toward what is valued. This can be an immediate conscious value, or what one conjectures unconsciously as ultimate value (Emmons 1999; Schneiders 1986).

The characteristics above have been present within the transformative experiences discussed thus far. The context for such experience was first identified as the Christian community, and then the world outside of that community – as the larger seeking-community. Concurrently, a well-established research literature has grown up around the broadening phenomena of spiritual experiences (Alexander 1980). Like the transformative experiences themselves, such studies started within the Christian community's theological discipline. Although research about self-transformation no longer necessarily depends on theological positions, we, too, turn to a more

academic exploration of the discipline of spirituality.

Spirituality as a research exercise takes place among varying disciplines and can be described in various manners. What is universally agreed to is that the scholars studying spirituality are interdisciplinary in their research. Any study of transformational experiences necessarily includes several disciplines interfacing with one another. Which disciplines produce the research and how the disciplines interact to obtain their information depends on the *problematic* circumscribed by the investigation – that is, what is of interest about the spiritual experience to the investigator? for what problem is a solution being sought? The mingling of methodologies will be addressed below. Initially however, spirituality studies can be differentiated along three continua (Schneiders 2005): the historical, the theological, and the anthropological; and they can also be considered from inclusive-exclusive and vertical-horizontal approaches.

The historical disciplines are probably most applied to studying spiritual experience or movements. This is likely because spiritual experience as such is a subjective experience by someone that is located somewhere in time. Spirituality can be looked at by experienced historians who can assist by placing it in context, broad or narrow, which helps the reader better grasp something of the "what" that occurred "when" (Lee & Kanazawa 2015). However, the spiritual experience can also be looked at by the spiritual scholar who may be interested in the manifestation of a particular type of experience and how this has manifested over time – for example, one could have an interest in those who lived a solitary life for transformative purposes and how this compares across Chan Buddhists (Heine and Wright 2010), Christian hermits (Williams 1962) and Hindu Sadhus (Flood 2008). This latter approach might be envisioned as historical spirituality scholarship.

The theological disciplines commonly study spirituality from a vantage that includes experiences located inside the base religion of that scholar. For Christians this would likely focus solely on transformative experiences related to "the life derived from grace." Whether or not the

spiritual experience was related to a theistic belief might be thought of as an “inclusion-exclusion criterion.” So-called “vertical-horizontal” considerations can also be applied. Herein, verticality contrasts differences among theistic religions: Judaism vs. Christianity vs. Islam; while horizontality compares similarities among them (codified behavioral traditions, creedal beliefs, and established rituals (e.g., Cohen and Heldrich 2002). While the vertical could explore the *relative similarity* of a hierarchical concept of “God above and humans below” within Christianity (e.g., Holder 2005), Judaism (e.g., Mintz and Schiffman 2005), and Islam (e.g., Nasr 1987) altogether different considerations would be determined for studying the nontheistic spirituality of Buddhism or Confucianism (e.g., Carmody and Carmody 1994/2015). A horizontal consideration could also take into account the *differences* among nontheistic spiritualities. For example, such studies recognize to what degree each spirituality relies on written scriptures or spoken inspirations (Thundy 1993).

The *anthropological disciplines* are, in principle, open to all transformative experiences, understanding them to be “the structure and dynamics of the human person as such” (Schneiders 1989, p. 682). The anthropological methodologies acknowledge the concept of spirituality as being “rooted in our primordial origins” and as “a fundamental human dimension” (Gellel 2018, p. 17). It is also fair to conceive of the anthropological disciplines as focused more on the whole person rather than the “interior life” as do most theological disciplines. From the theological vantage point if the “interior life” is contrasted with one’s “external life” spirituality research could be considered a dualistic undertaking – similar to the dichotomizing of “material” and “spiritual” as opposites. While anthropological approaches can also include dualistic formulations of spirituality, the more holistic styles of spirituality are included there (e.g., Carr 1986). As recently as the 1980s this dimension was referred to more in “religious” than “spiritual” terms. It is in light of the coming together of religion and spirituality in the academic arena that spirituality as an academic discipline has expanded dramatically (c.f., Pargament

1999; Schneiders 1989; Spalek and Imtoul 2008).

As to the interdisciplinary nature of spirituality and to the interface of the methodologies, each researcher considers which disciplines constitute the research program in question. Constitutive disciplines supply the frame of reference and thus the data of the spiritual experience. For example, primitive accounts of Christian bishops and their social organization might be the focus of *historical* researchers, while religious documents including scripture might serve as the focus for *theological* researchers, and perhaps descriptions of “natural highs” and in vivo spiritual participation would be the focus of *anthropological* researchers. But the *focus* brought to this positive data will also expose a specific problem to be explored; and this problem identifies which disciplines will be needed to address that problematic. Again, by way of example, political impact of the bishopric may require political science to be the lens of the *historical* researcher, the authenticity of “orthodox” and “heretical” manuscripts sought by a *theological* researcher may require literary criticism to ultimately discern authenticity, and the influences of “groupthink” on personal spiritual experience may draw the *anthropological* researcher to apply sociological criteria.

The very multidisciplinary nature of spirituality as an academic topic precludes adhering to any one discipline’s set of research tools. Of course, historical research, as an example, will adhere to historiological tools in exploring the spiritual phenomenon of interest – but those tools alone cannot take on the burden of determining truth value as modernist sciences presume. Not, at least, if the researcher intends to more fully understand the spiritual dimension under examination.

Before concluding this section, a final point would be good to make. Whether personally *experiencing* or formally *exploring* transformative experiences, there are personal consequences involved. Just as spiritual phenomena must require an *interdisciplinary* approach for better understanding, so too, spirituality researchers do well to recognize their *interpersonal* and *intrapersonal* involvement. This is not just a psychologist’s bias (e.g., Taves 2003) – although the author

self-implicates by making his point (cf., Allport 1955/1983; Gergen 2015). In current research, the human sciences acknowledge the limitations of their “science.” The objective ideal of *replicability* that science came to represent in the modern era was preceded by a long premodern history of its own based on *authoritative pronouncement* and is currently giving over to a postmodern sensibility that *subjective influences permeate all objective* inquiry (Mansager 1998).

This awareness takes on different expressions in the different disciplines and is well represented by Ricoeur’s (1976) attention to how an individual interprets texts. By acknowledging that “the surplus of meaning” (p. 45) in literature is only partly due to the “signification” of the words, and also to the interpretation of the consumer of the words, Ricoeur legitimizes a “science of the individual” (p. 79) the description of which Schneiders (2005) recognizes fits spirituality research completely: “Studies in spirituality . . . aim to . . . investigate the spiritual life as it is and has been concretely lived” (p. 18).

A Summary of Spirituality: Experiencing and Exploring

The final task of this article is to summarize spirituality as experience and as the exploration of that experience. Of course, spirituality has been a subject in the literature since its inception. Paul noted different forms of the spiritual life in communities he had founded as well as those which showed allegiance to other founders (1 Corinthians 1:12). Through all subsequent periods of the Christian era, there have been treatises on the spiritual life. Some of these remain classics that served as guides to possible futures for countless people seeking to live a spiritual life conforming to one or another historical period. Western Christian spiritual writers include Hildegard of Bingen (1098–1179) who wrote *The Book of Divine Works*, Thomas à Kempis whose *Imitation of Christ*, has already been referenced, and John of the Cross (1542–1591) who wrote *Dark Night of the Soul*. Eastern rite Christians also provided oral or written thesis on Christian spirituality: These

spiritual guides include Antony (983–1073) and Theodosius of Kiev (c. 1073) neither of whom wrote lasting volumes yet influenced monastic spirituality throughout Russia; St. Joseph of Volotsky (1439–1515) who wrote *The Enlightener*, a reform-oriented approach to monastic spirituality; and Nicodemus the Hagiorite (1749–1809) “managing editor” of the spiritual anthology, *Philokalia*, a collection of spiritual texts from the fourth–fifteenth centuries BCE. All wrote (or preached and their words were transcribed) about the Christian spiritual path in the manner each experienced and later came to know.

Today none of these tracts would qualify as studies in spirituality by standards delineated in the previous section. However, they each may be considered by the constitutive disciplines to be the provider of the experience of spirituality. For example, depending on the problematic under question, the countless examples of and aids to transformational experience found in *The Philokalia* (cf., Ware and Sherrard 1979) can be examined variously:

Historically inclined researchers could look at all these manifestations of monastic spirituality represented in *The Philokalia* itself to compare each across the ages (e.g., McGuckin 2012).

Theologically inclined researchers could explore the concept of “church” and its association with the monastic assembly as documented by *The Philokalia* (Banev 2012).

Anthropologically inclined researchers might include psychologists who focus on the issue of mental health within monastic spirituality (e.g., Cook 2011); feminist scholars who consider women’s place in the book’s development (e.g., Harrison 2012); literary form scholars who explore the range of literary devices utilized among the 4th–15th Century spiritual masters (e.g., Ugolnik 2016); or perhaps sociologists who look to the contrasts of the law and political movements found in *The Philokalia*’s different chapters (e.g., Witte and Alexander 2007).

Currently, spiritual research studies abound. The rise is a parallel phenomenon of countless disciplines and perspectives of the possible within them. The author is most familiar with the rise in research within psychology and by way of example, notes that spirituality studies have grown steadily since the early twentieth century. Under

the influence of William James's (1902/James 1982), *The Varieties of Religious Experience*, transformative experience was opened definitively to educated lay audiences. The psychology of religion, then, has over a century-long pedigree in grappling with spiritual experiences and connected topics. With greater and greater attention being paid to spirituality's possible pasts, presents, and futures (Glaveanu 2018), the psychological approach now identifies as the "psychology of religion and spirituality" and the American Psychology Association has published a journal by this name, which is now in its twelfth volume year. All this to say that, among the vast assembly of scholarly disciplines, transformative experience along with its documentation and interpretation has certainly stretched beyond the original structures of Christian spirituality. Still, they retain the discernable characteristics of *striving to integrate oneself in terms of self-transcendence toward one's ultimate value*.

State of Consciousness

Daniele Di Lernia

Milan, Italy

Abstract

Consciousness is a complex construct that has been defined in different ways throughout history. Among many, Damasio (Philos Trans R Soc Lond B Biol Sci 353:1879–1882, 1998) defined consciousness as the awareness of the self and, in this and many other perspectives, the self and the concept of awareness represent fundamental elements in the definition of consciousness. Moreover, their integration across a multidimensional perception through time allows us to consider consciousness as a nonunitary construct. Indeed, there is no such a thing as a single consciousness but rather several states of consciousness that constantly flow through each others and define the awareness of our self in a specific moment in

time. The entry will propose a historical overview of the concept of consciousness, focusing on two fundamental elements of this construct: the self and the awareness of the self. The entry will then introduce the concept of states of consciousness, which emerges from a non-unitary perspective of the original construct. From a nonunitary consciousness, the entry will present the concepts of dissociation, ecstasy, and trance, considering how these concepts can be reframed outside the Western point of view to trace a path to a transformative self.

Definition

Consciousness has been an object of debate across the history of humankind. Several disciplines tried to render the complexity of consciousness, from religion to philosophy and from biology to psychology and neuroscience. And, up today, there is no shared definition of consciousness but rather several interpretations that reflect the difficulty to render something so elusive. Therefore, it should not come as surprise if some authors, in this very long and controversial debate, defined consciousness as undefinable (Perry 1904). Notwithstanding, several attempts of definition have been made and among these, we can find some elements that will help us to better understand the nature of our consciousness.

A very immediate and appealing definition came from Damasio that defined consciousness as the awareness of the self (Damasio 1998). Others as well relied on the concept of awareness and Niedermeyer (1994) defined consciousness as the process of being aware of things, either

within (feelings, memories, etc.) or outside (objects and perceptions) us. Similarly, Koch defined consciousness as the subjective awareness of ourselves and our environment (Koch 2004). Similarly, albeit on a more epistemological perspective, Bisiach (1988) designated three sense of consciousness, moving from the consciousness of nonphysical entities to the consciousness of the phenomenological experience through senses (i.e., sensations, actions, and thoughts), and to the consciousness of our internal states.

All these definitions, which span across different theoretical and scientific frameworks, seem otherwise connected by a common thread and they rely on a fundamental shared concept: consciousness emerges from two distinct processes, awareness and self-perception. And this is the reason why, through history, the search for consciousness has inevitably become the search for the self and the awareness of the self.

In this entry, we will propose an overview of the history of consciousness, exploring the most important theoretical frameworks, moving through the search for the self and the self-awareness. The entry will explore the concept of consciousness as a nonunitary construct that generates different states of consciousness, such as ecstasy, trance, and dissociation. Lastly, the entry will explore the possible of consciousness.

However, the reader should always consider that, ultimately, the complexity of consciousness will always elude definition because “consciousness is not a simple function of the mind, but its organization” (Maldonato et al. 2018, p. 357). Consciousness would be an emergent propriety of a distributed system across different functions and this intrinsic characteristic opens the Pandora’s vase of the human mind, enriching a difficult search for consciousness with the arduous task to find the origins of the self and our self-awareness.

History of Consciousness and Theoretical Approaches

Considering the proposed definitions and how they rely on the concept of awareness and self,

we must not forget that even a simple statement such as the one from Damasio entangles a profound degree of complexity because it requires itself a definition of both awareness and self. This complexity is not only a matter of epistemology, biology, or science, but it is also the results of the historical and linguistic processes that, through the centuries, tried to define consciousness in a tireless search that was bounded by the simple fact that consciousness is a complex construct with infinite facets.

On this regard, Damasio himself noticed a peculiar distortion that underlines all the conversations that connect consciousness and awareness. The root of this relationship might, at least partially, reside in the language used. English, for example, distinguishes between consciousness and awareness, postulating two semantically different constructs, which therefore need to be further defined and at least partially differentiated. Conversely, Latin languages do not operate this distinction, and a simple word “*coscienza*” (from the Italian) describes at the same time the consciousness and the awareness. This linguistic digression suggests how, at least partially, dwelling in the concept of awareness aiming at defining consciousness is the results of historical and linguistic perspectives that shaped the view and the relative theoretical frameworks of many scientists. Bosinelli (1995), for example, defined three types of awareness, each one of them built upon the previous one (i.e., awareness of phenomenological objects, meta-awareness – as an awareness of being aware of, and self-awareness – as an awareness of our self), further indicating how a language can divide, connote, and separate different aspects of something that was originally united.

However, if language and history tried to separate the different faces of a singular unit, philosophy, neuroscience, and psychology tried – paradoxically – to put together again what was divided and several theoretical efforts tried to render the complexity of the consciousness.

Picton and Stuss (1994) suggested that consciousness may involve and require some sort of modeling, anticipatory processes that create models of the expected world, constantly

adapting ourselves to these models rather than perceive a pure perception. In this view, consciousness would be another model of ourselves, our world, and our presence in this world. A model of being self-aware is constantly built and self-aware is constantly built and updated by the brain with new information. Parallely, Damasio identified and defined two kinds of consciousness: a core consciousness and an extended consciousness (Damasio 1998). Core consciousness is the product of a transient process that does not require language or memory, and it is more related to short-term processes of memorization, perception, and awareness. Core consciousness is therefore built upon two other elements, a transient core self and a transient awareness. Conversely, the extended consciousness required a quite complex characterization integrating an autobiographical self that is a function of our self-awareness through time merged in a coherent narration that ties together the ability to recollect the past, perceive the present, and foresee the future. Everything combined in a coherent meta-representation through language and time, ultimately creating our very sense of self. Damasio elegantly illustrated this point when he defined the two fundamental axes that constitute the research on the human consciousness: the temporal dimension – namely how the brain creates an infinite flow of perceptions temporally and spatially unified – and the dimension of self – namely how the brain creates a sense of self, a reflective surface that encompasses all our perceptions in a coherent unit that belongs to us, that defines us, and that is us (Parvizi and Damasio 2001).

The search for the self was long due, from James' declination of physical, mental, and spiritual self (James 1984, 2013) to the modern neuroscientific models of self-consciousness. It is an arguably impervious task to render the complexity of a topic so dense and its infinite constellations of theoretical approaches. Metzinger proposed an extensive compendium of this search from which we can draw a simple and powerful conclusive fact. There is no such thing as a self. "Nobody ever was or had a Self" (Metzinger 2004). The fundamental propriety of

self is nothing more than conscious self-models that, nonetheless, are not recognized as models. This simple statement holds a disruptive message; our consciousness is not a unitary element that exists per se. Rather, it is emergent propriety of a complex system that constantly creates an infinite permutation of its own states, becoming aware of these very states. And these states are our states of consciousness.

States of Consciousness, Ecstasy, Trance, and Dissociation

Albeit the concept of a nonunitary consciousness that does not exist per se endangers the human ego, which gravitates around the desire to be utterly unique, recent evidence from neuroscience (Craig 2002, 2009) and the computational Bayesian models of mind (Friston 2009, 2010) supported Metzinger's idea. Integrating these different perspectives, we began to understand that the emerging processes that create our consciousness rely on the experience of "being someone." An innate, immediate, experience is that we constantly live from the moment we are born and, nonetheless, we struggle to completely understand despite the immense effort science has dedicated to this very goal.

Being someone is arguably innate propriety of being alive; however, this conscious experience has different aspects, like a stone carved with an infinite number of faces, each one with its one unique reflection. Emerging sensations from the body, our emotions, our thoughts, and our memories, each of these specific domains constitute a necessary element of the self and the self, as we have defined, constitutes the ground upon which we can create consciousness.

A concept that often recurs in the field of consciousness is the concept of altered state of consciousness as the natural and unnatural variations of the awareness of our self-perception.

The study of the altered stated of consciousness has perhaps a longer history than the research for consciousness itself, because the natural occurring deviations from our coherent day life

often captured the interests of many, from researchers to scholars, from doctors to saints.

Several definitions addressed this topic, some of them integrating a poetic and cultural perspective through the concept of *trance* or *ecstasy* as originally explored by Eliade (1964). Others utilized a psychological perspective with the construct of *altered state of consciousness* as proposed by Wallis (2003). In modern times, several definitions exist and among them, the concept of modalities of nonordinary consciousness proposed by Comba (2014) represents the most appealing framework. Under this umbrella term, consciousness is described as a flow of mental states in which awareness can oscillate and can vary naturally across time. In this constant stream of consciousness, some states are more ordinary – and recurrent – than others, while others manifest themselves only in particular occasions. However, these particular occasions are not necessarily tied to a traumatic or negative event, and the mind itself can oscillate frequently between different levels of consciousness that move from pathological states to highly functional ones that we see in the transformative experience or the moment of profound insight, passing through the daily altered states that every each of us experience when dreaming with open eyes or when we have no precise recollection of an action that we just did.

However, all the definitions proposed suffer from a fundamental problem, and they fail to specify the elements and the systems that constitute the altered states of consciousness. The ecstasy (or trance) in Eliade's view (1964) can indeed assume a variety of forms and different declinations. Moreover, it can be reached or induced by an equally large variety of methods that can alter our consciousness, projecting the individual in a different state of mind.

In Eliade's view (1964), the concept of ecstasy is more like a superordinate term that contains a multiplicity of variations, each of them with unclear boundaries. And this applies to all the other conditions as well.

This extreme ambiguity brings as a consequence the covert absence of comprehension from one side and an excess of stereotypization

on the other side. When we think about ecstasy or trance, we usually imagine some extreme declination with profoundly marked traits as the one we see in films and anthropological documentaries. Nonetheless, it would be a capital error to consider the altered state of consciousness, or ecstasy/trance itself, only in relation to the extreme displays that we know from the literature or the fiction.

The ecstasy or trance does not assume, indeed, only the extreme manifestations that we see in religious stories about the lives of saints. Neither they can be exclusively defined by those dramatical and theatrical possessions that we admire on the anthropological section of the history channel. Neither, again, they can be relegated to those particular states of consciousness that result from the consumption of intoxicant substances.

Therefore, aiming to bring more clarity stream of notions and definition, it could be useful here and now try to redefine the concept of states of consciousness, ecstasy, and trance. This process will help to reach a better comprehension of the terms introduced, evaluating how these constructs could be better defined by adopting the concept of *dissociation*.

Nonetheless, to do so, we must open ourselves to the *possibility* of a different perspective.

In psychology, the term dissociation has a specific and defined valence and, notwithstanding its ability to vary across different theoretical paradigms, it usually indicates a mechanism where specific psychological states of consciousness can separate and detach from each other or the mainstream of consciousness. This process, which can present itself often in a temporary manner and more rarely in a permanent way, can bring therefore an interruption – a break – in the ordinary flow of consciousness within the individual's psychological universe.

From this point of view, some definitions can shed light upon the concept of dissociation that can be in general:

designed as a distortion, a limitation, or a loss of the normal associative connections with a concomitant incongruency between an idea and the other, between ideas and emotional resonance, between

the content of our thoughts and our behaviour, where we can read at the same time a separation and an arbitrary connection between different elements of the psychic life. (Galimberti 1992, p. 849)

Similarly, Rondal Laing with his peculiar phenomenological conception described the concept of dissociation as a particular state of consciousness where “an individual, even in ordinary circumstances, can miss the sense of temporal continuity, or the sense of his personal coherency. [...] Can feel his self partially disjointed from his own body” (Laing 1990, p. 50).

However, for Laing, the dissociation was a pathological (schizophrenic) defense mechanism to an ontological insecurity in which an individual failed to positively integrate his or her sense of self and self-awareness, leading to a disruption in his perceptions. In this dissociated state, the mind is, at the same time, trapped inside the body but without the ability to perceive the body and the outside world as it own, leading into a disembodied perception where everything – including ourselves – is not real.

This must remind us that, albeit these definitions can open several different interpretations, in the Western societies, it remains difficult to detach the concept of dissociation (or different states of consciousness, or trance, or ecstasy) from the field of psychopathology. Because, for the general biomedical paradigm, any shift from the ordinary flow of consciousness is generally considered an aberrant functioning of an otherwise coherent mind.

The Possible of the Consciousness

Notwithstanding what has been said so far, it is of paramount importance to open to the possibility that a biomedical and psychopathological approach cannot render the complexity of human mind.

As stated, Western biomedical approaches often interpreted pathologically the different states of consciousness that exceeded the ordinary functioning. If these different states have been interpreted as a curse or a gift in the past,

nowadays the biomedical framework tries to categorize everything out of ordinary under the concept of dissociation, as a separation from the ordinary – and coherent – mind.

Nonetheless, evidence from neuroscience and experimental psychology (Di Lernia et al. 2016, 2018; Riva et al. 2017) suggest that our mind is a probabilistic system that constantly generates infinite permutations of our existence, of our perceptions, of our actions, and of our futures selves (De Ridder et al. 2014; Friston 2009, 2010; Friston et al. 2014, 2016; Ondobaka et al. 2015; Pezzulo et al. 2015). In this generative system, within an infinite flow of consciousness, different mental states succeed each other without continuity and interruptions, moving from the ordinary states of consciousness that we can easily define, to the ones that rarely touch our awareness (Adams et al. 2013; Edwards et al. 2012; Friston et al. 2012). These states of consciousness can dissociate from the ordinary states of the mind and, at the same time, create a new association between thoughts, feelings, memories, dreams, and hopes.

Although it is certain that crystallization of a dissociative state of consciousness can lead to a psychopathological state, it is equally true that – in most of the occurrences – different states of consciousness, dissociation, and even ecstasy and trance represent elements of our daily life that congruently fit in the common mental experience of every individual, without necessarily reaching any pathological condition.

Ecstasy, trance, and dissociation should not, therefore, be intended as discrete states, as a rigid expression of two opposite states of consciousness, the healthy and the pathological one. They should be better intended as an element in a continuum that moves from the ordinary modalities of functioning to the extreme cultural and psychopathological evidence that is reported in the anthropological and medical books.

The human being experiences different states of consciousness, small dissociative episodes and even ecstasy and trances every day and, during his or her entire existence, are described by different grades of intensity and forms. They could be the incredible images that appear in front our eyes

before falling asleep, or when we find our self-mind wandering without a precise recollection of the minutes before because we were completely absorbed in our thoughts, or, again, when we experience a moment of pure joy and awe in front of something beautiful and yet unsettling, or again when we are completely absorbed by a work we are doing in a sort of flow of consciousness that excludes everything around us.

Opening up to the possibility to consider dissociation, ecstasy, and trance as naturally occurring elements of our consciousness, without a psychopathological connotation, leads us to the concept of the optimal zone of consciousness (Di Lernia 2014).

Specifically, the optimal zone of consciousness represents a psychophysiological space where the dissociative and altered states of consciousness are equally balanced in a proactive manner with the ordinary consciousness, in a way that allows a hyperfunctioning of our cognitive and affective systems. Examples of these states are the experience of flow and awe (Chirico and Yaden 2018; Triberti et al. 2016), which can either bring us to the verge of a powerful insight (Chirico et al. 2018) or an incredible focus toward our self or the task at hand. At the same time, the optimal zone of consciousness can represent a state of possibility, a specific cognitive region of space and time when we can enact profound transformations regarding our cognitive beliefs, our self, and our emotions, leading to real transformative experiences (Gaggioli et al. 2016). However, by definition, the optimal arousal zone is a non-ordinary state of consciousness and, therefore, it is difficult to reach, to maintain, or to induce. Eliade (1964), arguing about trance and ecstasy, highlighted how shamans and healers underwent a complex and difficult training to gain knowledge of their dissociative states, ultimately learning how to balance and control them to create a space of optimal performance. Balancing the consciousness and the self-awareness with the dissociation is, practically, balancing the consciousness with the loss of consciousness, trying to reach a specific point where the boundaries are permeable to self-transformation, without otherwise lose ourselves.

This, inevitably, requires intense training or some sort of external guidance, as in non-Western societies (Eliade 1964). However, and before all, it requires us to detach to the Western conception and start considering our consciousness and its possible variations as useful instruments to a transformative self. Because consciousness is a state of possibility, it is the realm of what can be considered possible and therefore should not be confined or labeled but rather accepted in all its extension.

Conclusion

In conclusion, human consciousness is an incredible instrument of the possible. Its infinite permutations connote our daily life in a manner that is sometimes difficult to coherently render. Different definitions and paradigms tried to coherently frame the sense of consciousness, moving through the self to the awareness of the self, from the ecstasy of the shamans to the pathological conditions of the Western clinical perspectives. However, this narration tells us that consciousness is still a complex and largely undiscovered realm that should be approached with a sense of possibility, with a considerate understanding of its natural variations, its different states, and how these states create the powerful experience that is the human life. Because consciousness is an experience so unique and incredible that is composed of both from ordinary elements and extraordinary events that contribute, together, to define the essence of our very existence.

Storytelling

Anete Mikkala Camille Strand
Department of Communication and Psychology,
Aalborg University, Aalborg, Denmark

Abstract

This chapter aims at clarifying in what ways storytelling connects to the possible, both the notion of possibility and to the discovery of new possibilities. The connection is depicted more specifically through two strands of storytelling known, respectively, as *Living story* and *Material storytelling* and exemplified by a specific method OT/Sandboxing. Overall, storytelling as a practice entails both memory work, meaning making and imagination and draws on experiences as well as available cultural and material affordances to act as both reference-points and creative building blocks in figuring out what is and could be happening in any given situation. Storytelling, in general, denotes the mundane endeavor of making sense of something through storying. It inevitably also involves placing bets on the future that enables the storyteller and the partakers to make sense of not just the present and the

relevant past but includes making sense of relevant next steps in order to act meaningfully. A manner of grasping or figuring out what *is* before you, what *has been*, and what *could come*. In the dynamic of this threefold lies the possible and the discovery of new possibilities. Each moment of storying is a moment of invoking the world yet again and the story dynamic thereby offers the possibility of resistance to what is and can be.

Introduction

This chapter aims at clarifying in what ways storytelling connects to the possible, both the notion of possibility and to the discovery of new possibilities. The connection is depicted more specifically through two strands of storytelling known, respectively, as *Living story* and *Material storytelling* and exemplified by a specific method OT/Sandboxing. Overall, storytelling as a practice entails both memory work, meaning making and imagination and draws on experiences as well as available cultural and material affordances to act as both reference-points and creative building blocks in figuring out what is and could be happening in any given situation. Storytelling, in general, denotes the mundane endeavor of making sense of something through storying. It inevitably also involves placing bets on the future that enables the storyteller and the partakers to make sense of not just the present and the relevant past but includes making sense of relevant next steps in order to act meaningfully. A manner of grasping or figuring out what *is* before you, what *has been*, and what *could come*. In the dynamic of this threefold lies the possible and the discovery of new possibilities. Each moment of storying is a moment of invoking the world yet again and the story dynamic thereby offers the possibility of resistance to what is and can be.

The discovery of possibilities lies at the core of the action because storytelling also includes making some things matter and others not (in both sense of the term) as what is emphasized and included in any given moment of storying constitutes a field of possibility where some actions become meaningful and others not.

The chapter clarifies these connections throughout three parts. *First*, a clarification of how storytelling draws on the linguistic turn as well as how it relates to and embarks from narrative research. This leads to an introduction of the notion of *living story* and its inspiration from Tamara play – LA's longest running theater play. Here the notion of *antenarratives* is introduced, which closely relates to how possibility is understood and discovered as well as the employment of new possibilities in storytelling actions.

Second, the material, (quantum) turn upon living story is introduced in terms of how it emphasizes possibility as a *meaning-matter entanglement* emerging in *the appeal of the present*. The part clarifies how this enacts a *field of possible becoming* involving the renewal of time, space, and meaning as an enfolding of *spacetime-mattering* within the acts of storying. This clarification then forms a bridge to remark on the acknowledgment of matter and the active employment of material artifacts in storytelling settings.

Third, the chapter zooms in on a specific method OT/Sandboxing, which has been developed within the material turn upon the living story “tamara” approach. This part exemplifies how more precisely the field of possible becoming is invoked as a *configuration* by the material affordances of the method and how this affords the play with the renewal of time, space, and meaning as a meaning-matter entanglement. Here an example of such a storytelling endeavor is included stemming from a design workshop among Experience Design students at Aalborg University in Denmark.

The Linguistic Turn and the Emergence of Living Story

The linguistic turn is absolutely central in comprehending the connection between

storytelling and the possible, because the turn toward emphasizing the performative significance of language and discourse freed the teller from being captured in closed stories of history and opened possibilities for diversity and polyvocality (Molly & Jørgensen 2016, Boje & Sanchez 2019). It gave the teller and partakers of the stories the means to step outside the narratives at hand by paying attention to discursively imbedded perspectives that would otherwise entrap them (or others) in specific roles and identities and courses of actions. The linguistic turn is thus a natural departure-point in depicting both the founding characteristics of the living story approach, and how it came to be possible as a turn upon the more classical humanistic, and even folkloristic, narrative approach (led by Poul Ricoeur), into a linguistically informed liberating story approach that at its core holds the possibility for many outcomes.

The Linguistic Turn

The Linguistic turn was carried out from the middle of the twentieth century by two prominent strands; a critical, poststructuralistic, meaning- and power-oriented approach led by prominent figures such as Michel Foucault, Mikhail Bakhtin, and Jacques Derrida through their work on genealogy, heteroglossia, and deconstruction, respectively, as well as an approach more closely focused on the language use, per se, by prominent figures such as Ludwig Wittgenstein and John L. Austin in their study of language play and pragmatic language use of speech-acts, respectively. Two strands that are still struggling to come to terms with the nature of discourse and language and the role of action and power within language use.

Regardless, the book “How to do things with words” by Austin (1955) is widely recognized as marking a turn in the understanding of the endeavor of talking from a descriptive one to a performative one. Talking wit from being understood as merely describing or conveying the actions of the world as it is, into an understanding of talk as performative action, an action that did something to mark the courses of actions of this world. While both strands catches on to this notion

of performativity Erickson (2004) highlights that the difference between the two strands can be summarized in terms of whether or not the conduct of talk in local, social interaction are conceptualized as profoundly influenced, and thus mere actions of puppets of larger discursive structures (the critical theory argument), or understood as performative utterances by social actors in their own right doing actual, and unique things with words and signs that mattered for the ongoing social interaction in the situation (the language-in-use approach).

All these reconceptualizations of how discourse and language-use matters in the construction of meaning are cornerstones in understanding both the linguistic turn within storytelling, and understanding how the possible relates to storytelling, because it was under these various influences the living story approach emerged in 1991 by narrative inquiry researcher David M. Boje (1991), through his attempts at documenting his empirical studies of language in use as storytelling. Like no other scholar within the field of storytelling Boje has been occupied with understanding precisely this dynamic of emerging possibilities for renewal within the process of meaning-making.

The Emergence of the Living Story Approach

Until then stories had generally been understood as the act of making sense of what has been through narrative emplotment. While Boje acknowledged retrospective sensemaking, his empirical findings let him to claim that stories were tersely told, never whole and being told differently across contexts (Boje 1991). To him real life stories seemed more as bits and pieces put together and serving the purpose of making sense in a situation allowing the teller to navigate possible next moves:

... experience are recounted socially throughout the firm to formulate recognizable, cogent, fensible and seemingly rational collective accounts that will serve as precedent for individual assumption, decision, and action. ... Although individuals are limited information processors, each person retains a part of the storyline, a bit of interpretation, story performance practices, and some facts that confirms a line of reasoning. ... (Boje 1991: 106)

Boje concluded that stories, contrary to the general understanding of narrative as a whole-some, temporal plot, are living and everchanging. Hence he coined it *living story* and to further emphasize the living, open-ended dynamic of these storytelling actions he developed the term *ante-narratives* to depict the vital, subtle element of *ante* as counter to the finite *post-understanding* as part of the Beginning-Middle-End (BME) structure claimed by the main figure within narrative research, Paul Ricoeur (1984), and his followers within organizational storytelling (such as Barbara Czarniawska (1997, 2004) and Yannis Gabriel (2000).

Ante, then marks both the subtle openings performed in stories for other possible outcomes and the bets on the future that tellers thereby seem to place in and by their stories. In effect, this orients these stories toward a vast number of possible futures, and enable them to resist or outright oppose the dominant, formal narrative. Ante-narratives emerge then as a field of possibility – the possible, by employing other bits and pieces of fragments of experiences as possibilities of becoming in their storytelling actions. A renewed field of possibility through emerging ante-narratives as traits of what is yet to come (Strand and Henderson 2019: 125).

Freeing Storytelling from Narrative

By these claims David Boje (1991) broke new territory and disturbed the peace within narrative research in his famous Administrative Science Quarterly article, which he first presented at the Academy of Management conference in 1991. A presentation that led to a break-out of scholars from an otherwise solid group, and the founding of an alternative conference format coined as sc'MOI (standing conference for Management and Organizational Inquiry), which held its twentieth anniversary in Philadelphia in 2011. The new group took on the identity of the naughty kid-brother of the dominant Academy of Managements narrative inquiry group of scholars that were still holding Poul Ricoeur's work (Ricoeur 1984) on Narrative and Time in high regard (for example, Czarniawska, Gabriels, etc.).

First Amendment:

*“An Emphasis on **Performance**: Be it resolved that Ricoeur’s position on narrative and time needs to be expanded to consider the context or space of narrative performances. We are not studying already constructed narratives, rather, narratives are performances in the moment.”*

(Cunliffe, Luhmann and Boje, 2004: 272)

Second Amendment:

*“An Emphasis on **Multiplicity**: Be it resolved that perpetual referring within the threefold mimesis occurs across past, present, and future time and contexts, resulting in multiple threads of earlier narratives (M1) weaving together into multiple present emplotments (M2), and continually recreating multiple futures (M3).”*

(Cunliffe, Luhmann and Boje, 2004: 273-274).

Storytelling, Fig. 1 The two Amendments to Ricoeur’s threefold mimesis

The living story group later (in 2004) formalized its rejection of the general take on narrative in two amendments to Ricoeur’s work (Fig. 1).

In co-work with various colleagues, (e.g., Cunliffe et al. 2004, Boje and Durant 2006, Jørgensen and Boje 2010) and over the course of the years, Boje refined his take on narrative research to “free” storytelling practices from being “stuck” in a general narrative of BME linearity (Boje and Durant 2006). And, importantly, in a manner that would at the same time enhance the complexity of the story practice to the benefit of possibilities of many story lines. The main inspirational sources for this rework of narrative research were Sartre (Temporal multiplicity), Derrida (Deconstruction), and Bakhtin (Heteroglossia) – all prominent figures of the linguistic turn.

Boje’s living story approach thus emphasized performance and multiplicity, respectively, and came to understand storytelling holographically as a constant dance or a tension between retrospective-narrative-sensemaking, the immediate presentness of living-story-relationality or contextuality, and the prospective-antenarrative-sense-shaping. The latter marks the frontiers of the possible *new or next*. Hereby Boje constructs a nonlinear, tripart arrangement across past, present, and future. Depicted in the model below is a version from 2011 (Fig. 2).

Next, a brief encounter with another vital part of the connection between storytelling and the possible.

The Tamara-Land of Storytelling: A Land of Possible Becoming

In framing what Boje had seen in everyday storytelling endeavors as *Living story* Boje took on a mundane inspiration from Tamara play 1981 by

Storytelling, Fig. 2 Boje (2011)

John Krizanc regarding the Polish painter, Tamara de Lempicka’s historical meeting with the Italian poet Gabriele d’Annunzio. It became the longest running theater play in LA in the 1980s – most likely due to the play’s manner of completely disrupting the theater experience by using an entire mansion as its stage design. This meant that scenes would take place simultaneously throughout all three floors and the audience would need to follow one, and not some other actor, and subsequently make choices who to follow next. Hence, no two persons would experience exactly the same play as they were forced to continually put together fragments they had picked from the scenes they witnessed in the order to comprehend what was going on. A bet that could soon be altered. During the break in the theater play the audience would exchange ideas and bets with even further possibilities for alternating courses. Numerous amounts of storylines would thereby be created across the board of the audience, and they were invited to come back time

and again and experience the play anew in a different order. A discontinuous threefold dynamic of grasping or figuring out what *is* before you, what *has been*, and what *could be* and with new possibilities continually emerging.

Boje expanded on this fundamental rule of the Tamara play to count for real-life storytelling actions of all types and referred to them as “Tamara-lands” (Boje 1995) and in effect they were living story landscapes of terse, nonlinear, and open-ended storytelling, privileging a telling of otherwise untold stories, as each new teller potentially edits the originally performed story through their particular collection of fragments to which they insert their own experiences, characterizations, and/or emplotment (Lundholdt & Boje 2018: 21).

With the Tamara play story becomes both polyvocal and embedded in buildings, rooms, and landscapes of the spatial and temporal shifting contexts: *“Tamara-land raises the specter of the ‘socio-material’ against the naïve fantasy that storytelling is situated in one room, at one time, with all participants in the role of passive audience. This raises the theoretical concern for the ambiguity and uncertainty of storytelling spread out spatially in different rooms (and corridors), different floors, different buildings, and within those sites, at different times”* (Lundholdt & Boje 2018: 21–22).

As it happens Tamara play thereby constitutes a useful bridge to comprehend the material turn within storytelling and how that turn qualifies for an even more complex understanding of the possible and the play of emerging possibilities within storytelling.

The Material (Quantum) Turn upon the Linguistic Turn to Story

The material turn envelops a range of turns toward the physical, bodily, and biological realm. Other names for this turn is the embodiment turn, ontological turn, and the spatial turn (see, for example, Julskjær 2009). Feminism, and the development of new materialism has been a driving force of this turn, and undoubtedly the work of Karen Barad (2003, 2007) has influenced the move most profoundly. This is due to a turn not just toward the material as the name would indicate, but a turn

toward the entanglement of matter and meaning, and as such a turn toward dissolving two of the most profound pillars of modern thinking – that of absolute exteriority, or individuality, and that of the Cartesian split between thinking and the materialized.

Storytelling as an Entanglement of Meaning-Mattering

While the living story approach, through the two amendments (Fig. 1), still grant the human actor the center role: *“the origin of agentic actions and the prime authors of meaning and identity”* (Hultin and Mähring 2016: 2), as well as acknowledges that human subjects are imbedded in material surroundings and use material artifacts as sensemaking devices, the material turn brought on a call to go beyond viewing meaning-making as episodic, human-centered, and (inter)subjective and reorient toward a more holistic understanding of the messiness of meaning-mattering (Strand 2014a; b; c; Poulsen and Strand 2014).

A call that manifests yet another amendment to storytelling theory, this time around though, it is an amendment to the living story approach and an amendment, which at one and the same time reconfigure the relation between meaning and materiality (and in doing so disrupts the Cartesian split) – and allows time and space, respectively, both a co-constitutive and a co-constituted role in the processes of becoming, and thus in the framing of the possible.

The Quantum Amendment

An emphasis on **meaning-mattering**: be it resolved that Boje’s position on living story needs to embrace quantum entanglement on the expense of absolute exteriority and human-centeredness, respectively, and thus acknowledge the mutually, co-constitutive role of meaning and matter in the enfolding of spacetime-mattering. (Strand 2014a, b, c: xxx)

The Complexity of the Emergent Moments of Storying

The theoretical quantum physicist, Karen Barad is a prominent figure within the material quantum turn in storytelling and in the framing of the quantum amendment. Her theory of Agential Realism (Barad 2003, 2007) employs a radical take on emergence in meaning making (thus in

storytelling actions) than that of the antenarrative dynamic of living story. Emergence here entails meaning-mattering and the becoming of the world yet again through a *between-field of possibility* that is actualized in the storytelling moment through a vast amount of entangled agencies. These agencies are integral parts of an *intra-act* in the sense that they themselves get their unique significance – become – as “something” in the very same moment as they exert their influence within the story intra-act. This means that time, space, matter, and meaning are considered both co-constitutive forces (an entangled agency) and co-constituted definitions (an emergent becoming) in the very act of *meaning-mattering*. Barad coins this emergence an *enfolding of spacetime-mattering*; a unit of the real that matters in both senses of the term. Until the very moment of storying, all elements of the real are indeterminate (yet, not without causality). Hence, the storytelling act is an act of *worlding* where also time and space come to matter, which also means that time and space go way beyond being mere external measures:

...time and space, like matter and meaning, come into existence, are iteratively re-configured through each intra-action, thereby making it impossible to differentiate in any absolute sense between creation and renewal, beginning and returning, continuity and discontinuity, here and there, past and future. (Karen Barad 2007, Preface)

This is an understanding of emergence that basically entails a past that never was, a now that is not only here-now, and a future that will not simply be. The threefold of time, so well known from storytelling and narrative research, is here enacted as a rather complex (re)enfolding or restorying act through the *appeal of the present between* in the very moment of storying. In other words the present *between-field of possibility* matters for how stories enfold and what possibilities emerge (Fig. 3).

Thereby any moment of storying is a between field of possibility that automatically restories both the past and the possible future as it attempts at figuring out the now. An enactment then of a field of possible becoming, where the emerged antenarratives are the traits of what can

Storytelling, Fig. 3 A moment of storying. (Strand 2012)

possibly become. (Strand and Henderson 2019: 125).

In that sense the field of spacetime-mattering is a *between-field of the possible*.

Scenarios as an Agentic Storytelling Partaker

Spatial elements are an important entangled part of this field of possible becoming of any storytelling moment. Not just as context or as situated action as a living story, but as co-constituent agency to be acknowledged and reckoned with. Partly because these storytelling moments take place somewhere, which functions as *affective sites of engagements* (Strand 2012, 2020), where the agency of the place entails the materials, colors, shape, temperature and air quality, arts, and symbols in general, etc., of this place. And also because the particularities of the site of the storytelling action becomes an agentic part of a scenario that weave in other scales of times and places through memory rework of past and future experiences:

Each scene diffracts various temporalities within and across the field of spacetime-mattering. Scenes never rest, but are reconfigured within, dispersed across, and threaded through one another....Multiple heterogeneous iterations all: past, present, and future, not in a relation of linear unfolding, but threaded through one another in a nonlinear enfolding of spacetime-mattering, a topology that defies any suggestion of a smooth continuous manifold. (Barad, 2010: 240)

As sites of engagement these scenes affect partakers differently and triggers both memory-work,

cultural knowledge, and imagination as part of the ongoing meaning-mattering of the emergent story process. All partakers – human and other than human – of any such between-field are understood both as materials being woven in a certain way – hence, enacted as *something* – and agentive coauthors of the story through that particular enactment, which could have been different.

So while stories are constructive attempts of figuring out what is going on, they are at the same time a very real, living act of allocating what matters and what doesn't seem to matter. And in that sense the process of enfolding of a story is a very real construction of a *field of possible becoming*. A formative occasion (Hultin and Mähring 2016) in the sense that meaning materializes as both choices and form. Meaning becomes *mattered*, so to say, and in doing so a unique field of possible becoming will have emerged that could have been different.

That way the story is being woven as a unique, emergent enfolding, neither true nor not true, just what became in that particular moment given the play with a very particular *between-field of the possible*. An enfolding that also holds the possibility of grasping places and our relations to them anew as sites of our actions to come.

Material-Based Storytelling as an Act of Worlding

The living story approach coined as Material Storytelling (Strand 2012) quite literally work with such meaning-mattering by building actual *meaning-matter tamara-land configurations* through placing figurines on storyboards with sand. These affordances enable the participants to comprehend their experiences in a story format by placing, sorting, and reworking fragments of their experiences, and in doing so placing matters of importance, as well as their bets on relevant next steps and thus play with the field of possible becoming. Through literally materializing the between-field of possibility, each moment of working out this story becomes a moment of invoking the world yet again from the rework of the included parts.

Below follows an example of using this miniature world-building storytelling practice. The specific method is coined as Object theater (OT)/Sandboxing (Strand 2014a; b; Strand & Sparholt 2017, Strand, et.al. 2018, Strand 2021) and are the central story platform of the Material Storytelling methodology (Strand 2012), which has been part of the study programs across the Department of Communication and Psychology at Aalborg University in Denmark since 2012.

The Worlding Engagement of a Restorying Act

The following case-example is from a learning setting of Experience Design students at Aalborg University. The students are working on a redesign of a particular building situated in the midst of an industrial complex from the early twentieth century, which a local entrepreneur has envisioned as becoming one of the top ten “must-see” tourists sites of Europe. One that puts Aalborg on the worlds map and at the same time brings an international flair to the city. The plan is to fuse the old industrial buildings with modern, newbuilds to enact a city within the city. “Cloud City” is to have a large, fixed art piece by Saraceno as the centerpiece and main attractor. The art piece consists of 12 glass cubes forming a 30 meter tall construction that visitors can walk through and get a sublime overview of the city of Aalborg and its natural surroundings (Fig. 4).

Bearing this grand vision in mind, the task given to the students at the offset of the design-course was to come up with a design and a purpose for one particular building named “Malteriet” (encircled) as a unique and distinct part of the Cloud City complex.

The Miniature Worldbuilding Scenario

The OT/Sandboxing workshop followed after on and a half week of lectures, and 1 week of empirical fieldwork in and around the site. The students were invited into the storytelling lab fashioned with a large buffet of figures of all kinds and surrounded by storytelling platforms – one for each group of students. A field of possibility for configuring a common story of a shared task and challenge (Fig. 5).

Storytelling, Fig. 4 A mock-up of the vision of the Cloud City complex (part of case presentation for students 14 Oct 2020)

Storytelling, Fig. 5 Photos of the storytelling lab organized for the event

The basic idea of the OT/Sandboxing method is to employ a wide variety of material objects as configurative elements and as prompts for memory work of cultural and personal experiences to feature in as part of a creative, storytelling process. In the words of Haraway: “*Figures collect the people through their invitation to inhabit the corporal story told in their lineaments*” (Haraway 2008: 4). A figure then is a memory-device (Middleton and Brown 2005) that together with other such figurines configures a miniature Tamara-land of possibility within the frame of the sandbox. A

platform through which the story then emerges via the storytellers play with the antenarrative cues found in the lineaments of the figures, respectively, and in the lineaments across the entire configuration. Also the emplacement then in relation to each other becomes vital, antenarrative cues to interpret, experiment, and play with as the story takes shape and morph into being in the meaning-mattering process.

This method is useful in helping to navigate and comprehend the vast amount of impulses, information, and impressions that characterizes

Storytelling, Fig. 6 Photos from the living story session in material story lab 14 Oct. 2020

the fuzzy front-end of creative processes (Sanders and Stappers 2008), and in dealing with “wicked problems” (Buchanan 1992) as it affords the platform for the partakers to creatively negotiate a common ground for their co-work through enacting a common story of what challenges and possibilities concern the case and what ideas and criteria should be the core of the design.

After being designated a sandbox, the various groups of design students are given the instruction to let themselves be “invited” to choose among the “lineaments” of the vast amount of figurines on the buffet to embody important fieldwork experiences as well as their background knowledge of the case. While selecting figurines, all group members will silently go back and forth between placing figurines within the sandbox and selecting more from the buffet, and as such a common *tamara-land* of possibility slowly emerges in the sandbox, across bits and pieces of memory fragments among the group. In order to keep the *antenarratives* “dancing” off the lineaments, and exploring the possibilities of the configuration they are instructed to keep asking each other the question: “what else could it be?”. A deliberate invitation to reorient toward other *antenarrative* cues (Fig. 6).

Below is an example of such a material-based, emergent story process.

Eternal, Joyful Change: An Example of a Miniature Tamara-Land of Possibility

Contrary to the fixed, see-through art centerpiece of Cloud City, the lineaments of the following example of a sandbox configuration (Behnke and

Nielsen 2020) invoked a story about adding a motor of variety to enable a multiplex of stories to be constructed across the vast variety of visitors – local and foreigners – upon visiting Cloud City. What started as a simple idea of creating a site for a shopping experience turned during the meaning-mattering process into a rather impressive and sophisticated viral branding-concept.

The two photos below encapsulate the play with the miniature *Tamara-land* of possibility that the students were building during the workshop. The encircled parts show how the invoked *antenarratives* of the lineaments materialize two distinct storylines during the meaning-mattering of the story process. Each making an opening and a bet on a possible other future of Cloud City. Each making different things come to matter (Fig. 7).

The center of the sandbox configuration contains two figurines; a heart emphasizing it as central for the experience design to touch the visitor’s hearts. And a tulip, which is a seasonal plant depicting the cycles of events as the centerpiece of the design:

As a bulbous plant the tulip became a metaphor for continuous renewal; just like the bulbous grows, slowly becoming a flower and then dies out, whereby the cycle starts anew, the essence of the experience design is the cycle of continuous renewal: The experience starts with a premiere of a themed item, which then lives for a months and then it ‘dies’, then broken down and the whole thing starts anew. This element is to permeate the experience design and be the focus of it. (Students explanation in project report, Behnke and Nielsen 2020)

Storytelling, Fig. 7 Photo 1 and 2 of the sandbox (re)configuration of the field of possibility for “Malteriet”

Another important figure in the configuration is the rat. During the course of the living story process, the rat alters its position. In the first initial configuration (photo 1) the rat was placed within the tulip plant and storied as a negative element “eating away of the idea” and thus damaging it. The students here actualize cultural knowledge of the rat as a spreader of disease. One day prior to the storytelling workshop the students had briefly pitched the basic idea of using clothing items, etc., as a branding concept inspired by Supreme (among others). One of the audience had ditched the idea entirely and made the students aware of the threat of the concept being “badmouthed.” Also it referred to a general negative tone in Aalborg about the entire Cloud City project as internationally oriented. An insight that the contractor had shared in the initial pitch of the challenge. The lineaments of the rat embodied both these insights of the threat of badmouthing in the configuration, which is a good example of how the figurines function as multilayered memory devices.

In photo 2 the perspective of this badmouthing is restored to become an asset. This happens when the rat is moved out of the plant and placed in a position of spectator of it instead. Having acknowledged the circumstances of the badmouthing, the students conclude that they need to alter that situation somehow. The students

make us of the general instruction to ask “what else could it be” in order to explore the possibilities of the configuration. The move is elicited when in a kind of what if. The replacements invoke another ante to emerge as an opening for an alternate outcome. Rats are no longer eating away the plant, but are witnessing its cycles and are running from place to place spreading rumors about it – something that potentially catches on, goes viral spreading the word of Cloud City and Malteriet as a place of varied, continuous action, worth visiting. In that sense the relation of the rat and the tulip is reconfigured as beneficent, and the materially restored relation enacts the core of the design.

As an importantly entangled part of that restorying of the rat as agent, the football (storied as the playful element of the design) also changed its direction in photo 2. In photo 1 the football points toward the shopping-cart (“the purpose for visits is collecting fun experiences and buying fashion items”). Notice how the “front” of the football in photo 2 has turned and is now directly pointing toward the rat. A cue, as to what the playful element of the design turned out to be during the living story process: a rodent employed as a spreader in a meaningful play in the sense of “catch and pass it on.” Keep the ball moving. Thus, by turning the ball toward the rodent instead of the shopping cart marked an altering of the

Storytelling, Fig. 8 Model depicting the concept of motor of the ever-changing events and stories, (of students own making, Behnke and Nielsen 2020)

course of the story of the entire experience design from just an isolated shopping experience to the spreading and creating of stories worth telling, with the purpose of weaving a bunch of different stories of Cloud City as a manner of getting a continuous, yet varied flow of attention among a vast variety of groups both locally, nationally, and internationally in full alignment with the vision of Cloud City. As stated, living stories inevitably also involve placing bets on the future, which enables the storyteller and the partakers to make sense of not just the present and the relevant past but includes making sense of relevant next steps. The configuration of the axis: football, heart, and rodent (as spectator of the tulip) entailed just that with the rat as the reconfigured playful agent of keeping the ball moving.

The groups concept (Behnke and Nielsen 2020) of allocating the building “Malteriet” as a driver for the continuous branding of Cloud City meant constructing the building as an ever-shifting site of engagement. One with a wide range of monthly events promoting a uniquely designed item of sorts (as part of a growing CC Collection) that each would appeal to a specific – yet, over time – varied target group, which then

continually would “mouth” a wide range of different, yet connected stories about Cloud City.

The following model depicts how the meaning of the concept materialized (Fig. 8).

As such the concept being storied involves the renewal of both time, space and meaning for “Malteriet” and as such the concept is an enfolding of spacetime-mattering, which encapsulates a field of possible becoming for the building, and in turn for Cloud City. A good example of how storytelling practice, as a performative *worlding engagement*, connects to the possible, and to the discovery of new possibilities with possible impact on that world.

Storytelling and the Possible

The material-based storytelling in the above example entails both memory work, meaning making and imagination. The students include their experiences regarding the case as well as available cultural knowledge (of tulip, rats and football-games, viral marketing, etc.) through the material affordances of the methods. As memory-devices the figures here act as both reference-

points and creative building blocks in helping the students (literally) figuring out what is and could become key elements of the design and the function of the building. They (literally) place and replace bets on the future “next” for Cloud City. Regarding this manner of affording such a living process within design processes, Poulsen & Strand notes: “*The novelty of transformation in developing new conceptual comprehensions must be nurtured by the affordances of creative methods to embrace the designerly way of working and thinking and to interweave analysis (of empirical data) into synthesis*” (Poulsen and Strand 2014: authors capture). In alignment with what characterizes the first part of the creative design process, this manner of affording the process entails a reframing of the initial understanding of the problem in that a counter story emerges, when the students play with the field of possibilities of this miniature Tamara-landscape, and the core elements of a creative solution are storied. This above example thereby shows how more precisely the field of possible becoming is invoked by the material affordances of the OT/Sandboxing method and how this method thereby affords the possible to emerge and be played with as renewal of time, space, and meaning as a meaning-matter entanglement through the lineaments of the figurines and across their relations in the entire configuration as gateways to the possible and to discovering new possibilities.

Summary

The chapter clarifies in what ways storytelling connects to the possible. Specifically how the storytelling approach Living story and subsequently, Material-based storytelling entails working and reworking a field of possible becoming that connects to the discovery and employment of new possibilities. While closely tied to what is prompted in and by the present moment (the task at hand) – for example, through the employment of material artifacts – these living, story performances simultaneously draw on that which has passed and the speculation of that yet to be, without any of the two being in a fixed

state, which of course opens for a myriad of ideas to be at play and thus many possible outcomes. As such the act of storying affords the possibility of renewal of both time, space, and meaning of any scenario. There is therefore an intimate relation between storytelling, the possible, and the discovery of new possible becoming’s of the world.

Street Art

Sarah H. Awad
Aalborg University, Aalborg, Denmark

Abstract

The interest in street art has long involved a wide range of urban visual expressions such as murals, graffiti, tagging, and even urban defacement. These diverse aesthetic forms of expression have therefore attracted numerous theoretical and methodological approaches. Some analyze it from the standpoint of street art as an illegal act of vandalism, some as a political act of resistance, and some as a form of art and a new cultural capital. From a socio-cultural psychology perspective, street art could be analyzed as a social act that intervenes in the urban space, thus opening up possibilities for individuals to shape their environment, and in turn having that new environment with its new affordances shape individuals back.

This entry will discuss different conceptualizations of street art, especially looking at how the definition of street art has developed over time. Then it will outline some of the methodological approaches to analyzing street

art within visual culture. The entry focuses in particular on political messages of street art rather than their artistic forms, and the possibilities those messages could open up in visual culture and public discourse.

Keywords

Street art · Graffiti · Visual culture · Political art · Sociocultural psychology

Today, street art is a popular trend that attracts many enthusiasts. One comes across it in news and online media, in academic research, and in tourist guides in many cities around the world. It has gained much interest and status within contemporary art and visual culture, but this has not always been the case. What is referred to today as street art is often quite different from underground graffiti and name tagging that is associated more with vandalism. Still, the term *street art* is used to denote a wide range of urban interventions, in many instances incorporating quite different aesthetic forms. Street art is used loosely to refer to illegal graffiti paintings, name tagging, commissioned mural paintings, posers and paste-ups, as well as different forms of defacement of monuments and public structures.

The focus in this chapter is to look at street art from the angle of the encyclopedia's core topic: *the possible*, thus looking at street art as an intervention in the city, that reproduces its space and potentially opens up new affordances and possibilities. For this purpose, the focus is on unauthorized political street art in its many different forms addressing – but not limited to – different socio-political issues in relation to its surrounding context. In that sense, the chapter will not put street art into a strict definition with a distinct artistic form, nevertheless it will still provide broad definitions and discuss its historical development. It will then give a brief review of some of the methodological approaches used to understand street art in context. Finally, it will present a discussion of street art as an act of resistance in the public space and its potential to open up new ways of seeing and imagining alternative possibilities.

Definition and History

Broadly defined, street art refers to self-authorized pictures, characters, and different forms that are created in or applied to surfaces in the urban space (Blanché 2015). They are created to intentionally communicate with the wider public and are implemented in a performative, site-specific, temporary, and participatory manner (ibid.). Street art is interesting from a sociocultural psychological perspective because it is one of the many different ways through which humans shape their environment by creating signs – signs that in turn shape how humans relate to the places they live in. The surrounding city environment does not just serve a practical function in everyday life, but it forms part of our identity, behavior, memory, and everyday wellbeing.

Street art and graffiti might be relatively new concepts associated with urbanization and city life, but humans have been creating marks on walls and surfaces throughout history (Donald 1991). The word graffiti is derived from Greek word “γράφειν,” which means to inscribe. The Greek term was used to describe the drawings and writings inscribed on ancient walls and temples, such as those found on the Pharaonic and Roman remains (Wacławek 2011). Today's contemporary graffiti, however, refers to what started as a style of writing and name tagging by spray cans in the underground subculture in USA in the 1960s (Blanché 2015). This graffiti subculture has long been associated with youth creating disorder and vandalism in the city, and their graffiti has been a continuous source of annoyance to police and property owners (Fig. 1). Their graffiti has also shaped many places to be perceived by some as dodgy and unsafe parts of neighborhoods.

However, graffiti has developed into other forms of expression that are not “just” name tagging, but ones that have more elaborate artistic visuals and ones that communicate political and social messages. Those new forms could be characterized as addressing a wider public audience than the subculture of graffiti painters. This development has impacted the reputation of graffiti; from one that denotes vandalism and antisocial behavior, to one that denotes an artistic and

political form of expression. This new form has turned areas such as Shoreditch in London (Fig. 2) or Brooklyn in New York into areas of street art tourism. Rather than vandals, those street artists are seen as assets in the branding of different areas. And rather than a marker of unsafe areas, street artists became key role players in making certain areas more desirable to middle class and thus vulnerable to gentrification (Stevenson 2013).

To distinguish this form of street art from traditional graffiti, some scholars use the term *postgraffiti* (Reinecke 2007). The term *postgraffiti* is not used to imply that underground graffiti and tagging are something of the past, but rather to

highlight the new street art form and its distinct subculture that is positioned between art and commerce (Reinecke 2007). Its hierarchy could also be seen in its differential legal treatment from what is considered disruptive illegal graffiti (Waldner and Dobratz 2013). Furthermore, the *postgraffiti* street art attracts different forms of appropriation by art museums and commercial processes of commodification – in some cases to the extent that some street artists would erase their pieces to avoid exploitation (see Vimercati 2016). Any such commercial or commissioned effort to appropriate street art is found by many to divert from what is essential about graffiti and street art; that they are self-authorized, unofficial,

unsolicited, and un-commissioned (Blanché 2015). As others have also noticed, the process of commercialization also threatens to “neutralize” any political message the art form might have (Lewisohn 2008).

The interest of this entry is in the content rather than the form of the street art or graffiti. More specifically on the political content of street art and its growing use as an act of resistance in a global subculture of protest and movements (Doerr et al. 2013; Khatib 2013; Awad and Wagoner 2018). Even though unauthorized street art, whether with an explicit political content or not, is inherently a political act. It challenges the authority’s power over public space, distinguishing political street art (from tagging, for example) that highlights its oppositional counter-hegemonic messages (Waldner and Dobratz 2013) against certain institutions, groups, or ideologies such as capitalism (Fig. 3).

Research on Street Art

The tensions in defining what graffiti or street art is can also be seen in how it has been construed as a research topic within academia, is graffiti and street art antisocial behavior, is it a political act of resistance, or is it a form of art. This has attracted researchers from a wide range of disciplines such as cultural studies, art history, criminology, psychology, urban studies, and sociology, all of

which come with a variety of theoretical and methodological approaches to interpret street art.

The progression of academic interest in contemporary street art and graffiti is traced by Avramidis and Tsilimpounidi (2017) and conceptualized into three different waves. The first academic wave was, according to the authors, characterized by communication and sociology scholars looking at the complexities between the graffiti artists as practitioners and the more hegemonic authorities. Through the gaze of geographers and urban researchers, this research focus was further shifted from the practitioners themselves to the “graffiti site” and its landscape. Furthermore, political science researchers started to look at the political protest aspect of street art and activism. The second wave of scholarship is characterized by research that conceptualized street art within broader discourses in society, looking at the cultural and identity dynamics of the practice and its relation to the wider society. The third, current wave, coincides with the establishment of street art in the visual culture and its acknowledgment as a distinct field of study. This wave opened up wider connections to the topic from a variety of disciplines, which relate street art to issues such as temporality, materiality, space production, documentation, and commodification (Avramidis and Tsilimpounidi 2017).

Methodologically, a range of approaches has been utilized to analyze street art images. One approach has been to develop a historical

Street Art, Fig. 3 Athens, Greece, December 2018. (Photo by author)

conceptualization of street art, looking at it within the historical narratives of its time, and conceptualizing it as a performative process of narrative disruption (Ross et al. 2017). There is also iconographical analysis that attempts to categorize different types of graffiti and street art (Gottlieb 2008). Another approach is a cognitive semiotic one that looks into how narratives are told through the street art images and how those stories shape collective identity and collective memory (Stampoulidis 2019). Also, the interest in the dialogical aspect of the street art has driven research into longitudinal documentation methods seeing street art images as instances in an interaction (Hansen and Flynn 2015). The dialogical aspect of street art has also prompted the development of methods for following the social life of the images as they are transformed and reproduced (Fig. 4) to

represent and position different social groups in a contentious dialogue (Awad and Wagoner 2018; Awad 2020). This latter interest focuses on the political content of street art images and traces how images travel across time and space appropriating new meanings and forms in a continuous public political dialogue (see example of the fleeing refugee family image in Fig. 4).

Street Art and Resistance

In line with the dialogical approach, street art can be seen as voices in the visual culture that starts in the urban space and extends to the wider political discourse. Thus, street art carries the potential and the possibility to be used as a tool of intervention into the public space and as a voice of resistance to

(Photo by author)

hegemonic discourses. Activists around the world have utilized street art as a way to be seen and heard in the public space. Street art has been used in protests to appropriate public space and create alternative representations of different groups. An example of this can be seen in recent political street art that emerged in key areas of protest such as Tahrir Square in Egypt in 2011 (Fig. 5), Zuccotti Park in New York in 2011, or Gezi park in Turkey in 2013, or Freedom square in Sudan in 2019.

When we speak of the political content of street art, we can understand politics as a struggle over presence and visibility, a struggle over the representation of the society and who has the resources and access to represent it (Ranciere 2004). So street art comes as unauthorized expressions of a different representation breaking with the monopoly of public discourse by the authority. It provides a counter-narrative and a voice of dissent to dominant urban aesthetics and norms (Avramidis and Tsilimpounidi 2017), as well as a social act of resistance that is oriented towards change (Awad and Wagoner 2017). By proclaiming city space, street art also transforms the conception of public space, from a place predominantly produced and controlled by authority (Lefebvre 1974/1991) to a common space that affords new ways of saying, doing, thinking, and seeing (Agustin 2017). Hence, it can very well be perceived as an active form of both the possibility and the actuality of political participation (Waldner and Dobratz 2013).

Following the social life of street art images as they are produced, perceived, erased, documented, and transformed to other mediums provides an analytical lens into the dialogues they construct in society and the new ways of seeing they potentially provide. Street art images as tools of resistance have the potential to visually reconstruct the representation of power and bring visibility to marginalized groups (Fig. 6). They also construct affective symbols for different causes that mobilize different solidarity groups. They also visually position different social actors in relation to different social issues and commemorate different events thus co-constructing collective memory and a community's identity (Awad and Wagoner 2018).

Street Art and the Possible

It is precisely through the disruptive act of creating street art that the (im)possible is redefined, that is, the potential of appropriating spaces and reshaping the city environment with a new voice, a new possibility thus giving new affordances to the urban environment and new possibilities for action (Glăveanu 2020). When artists share their version of social realities and their imagination of alternative ones, in an environment where only one version of reality is allowed in the public space, street art becomes an outlet through which individuals can represent themselves and others, imagining different social positions, with

Street Art,

The mural is part of the Palestinian artist Emily Jacir's project which commemorates the over 30,000 books that were looted by Israeli authorities from Palestinian homes, libraries, and institutions after their displacement in 1948)

different power distributions. And even when this imagination is not actualized, it can disrupt the hegemonic discourse and can symbolically destroy any glorified image of authority.

It is unrealistic, however, to paint an image of street art as a revolutionary act of resistance that promises radical social change in and by itself. It is important to look closely at the potential of street art, especially in relation to its ability to shape an environment in a way that matters. To do this we need to first acknowledge how every day meaning is constructed and re-constructed in culture not only through language but also through all the different images we see every day in our visual culture. Our surrounding city visuals do not just serve as a background to our urban experience. They form part of how we identify ourselves with different places, how we feel represented and heard, and thus how we feel at home or being foreign, and how we feel connected and enabled or constrained. We identify ourselves with certain parts of the city: certain structures, streets, or imagery. And as we inhabit those parts, they come to inhabit our life stories and experiences. Within that understanding of meaning production in urban space and visual culture, we can see how street art can be a catalyst of new ways of seeing and acting. It thus

opens up new ways of experiencing and relating to the city and to the wider society. It triggers an active participation in our everyday experience. Each street art message calls for a personal interpretation of it, an interpretation that tells more about us than it tells about the street art piece, one that is affected by our current identities, ideologies, and social positions. The continuity and insistence of those images make them highly influential, yet they are often unnoticeable in our everyday life.

We should, however, refrain from romanticizing street art as an exclusively positive power of social change. The same potential of street art to appropriate city walls and produce space of inclusion can also be used to create spaces of exclusion and hostility. In the examples in Fig. 4, posters were used not only by humanitarian groups to welcome refugees in Europe, but also by anti-immigration groups who appropriated the same design to warn against refugees being “terrorists.” The same street art tools and potentials that could be used to open up new ways of inclusion, political participation, and solidarity are also used to advocate hate and discrimination against minority groups. Nevertheless, with the conception of street art as an ongoing dialogue, participatory, and transformative, there is always space

Street Art, Fig. 7 Malaga, Spain, June 2016. (Photo by author)

in the city for responses, for a new voice, and a new layer to the wall (Fig. 7).

That is precisely what distinguishes street art as a form of art and as a voice in political discourse: its temporality in an ongoing dialogue, its transformative nature with every pedestrian, and its participatory nature in a very place-specific context. It is an instance in a dialogue that is waiting to be responded to, erased, or transformed. It is mutually created and transformed by every person experiencing it. It brings in the agency of individuals in an urban domain that is predominantly shaped by those in power.

So to focus on street art as an act of resistance to dominant discourse is to acknowledge the mere power of imagination that lies in a street art image that moves us beyond the perception of the here and now. Even in situations of extreme oppression, people seek artistic expression to resist dominant discourses and express themselves (Scott 1990). One that reconstructs the past and suggests that an alternative reality is possible. And maybe that brief encounter with this image will not change the present, but it will make the present more bearable knowing others might also share their dream.

Street Protest

Patricio Saavedra¹ and John Drury²

¹Institute of Social Sciences, University of O'Higgins, Rancagua, Chile

²School of Psychology, University of Sussex, Brighton, UK

Abstract

Street protests are a type of collective action. Street protests are rather a fuzzy category, which means there is sometimes no hard and fast boundary with other forms of collective action. However, in both academic and activist circles and discourse, it is conventional to distinguish street protests from other collective actions as riots, strikes, and direct action. A protest – such as a demonstration march – is a

way of saying “no,” whereas riots, strikes, and direct actions go beyond saying to *doing*. However, as protests take place in intergroup contexts, participants sometimes transition from symbol to instrumental actions.

Keywords

Collective action · Demonstration · Mobilization

Overview

This entry will cover two main areas: First, the basics of street protests from a social-psychological perspective, and second, the mechanisms through which protests may relate to social change. We start by defining protests and differentiating them from other activities and concepts commonly (interchangeably) employed in the specialist literature. Then, we summarize the main approaches that have addressed the phenomena of protests from a psychological perspective. After that, we shed light on three key aspects of protest we consider are important but neglected from a social-psychological point of view: The relevance of the political context where protests are carried out; nonparticipants' support for street protests; and the role of media coverage of protesters' actions.

How Can We Differentiate Street Protests from Other Phenomena?

Street protests are a type of collective action; therefore, it is crucial to define first what collective action is, and then differentiate protests from more complex phenomena such as social movements. From a sociological point of view, Snow and collaborators (2004) argue that collective action can be defined as “any goal-directed activity engaged in jointly by two or more individuals. It entails the pursuit of a common objective through joint action” (p. 6). Even though this definition is useful to understand the basis of collective action, we should also consider the definition of Wright, Taylor, and Moghaddam

(1990), who, from a social-psychological perspective, hold that the understanding of collective action cannot be reduced to the number of people involved, and that the purpose (who the action is for) is more important. Hence, beyond considering joint actions as a requirement, individual actions carried out on behalf of specific groups should also be considered as collective action.

Street protests are inherently political and contentious but symbolic in the sense that they communicate resistance or opposition. This means that protests are aimed at advocating for changes in specific policies and living conditions at the societal level, while they seek to mobilize public opinion or other third parties in their favor (Lipsky 1968). Concerning their organization, protests may be more or less structured, being coordinated by diverse political or nonpolitical actors using various channels (e.g., the Internet; Kim 2019), while the existence of formal leaders is not a requirement (e.g., Kim and Kim 2009; Lee and Chan 2018). Whatever the mechanisms of coordination and organization, street protesters typically assemble at a specific point to take to the streets and raise their demands.

Coming back to the distinction between street protests and social movements, it is worth noting that whereas the former are activities that social movements may organize at a specific time and place to reach their goals, social movements are broader phenomena which last longer than a single event, may coordinate diverse activities throughout time (e.g., rallies, boycotts, and road blockades, occupy buildings), and employ varied strategies (i.e., peaceful, violent, or a combination of both) (e.g., Seidman 2015). Furthermore, Rucht (1998) suggests two key characteristics that differentiate social movements from protests. First, social movements seek a new societal order instead of being centered on solving specific issues (e.g., a tax increase) as protest events are. Second, unlike protests, social movements are typically embedded in an extensive network of groups and organizations that may help them to reach the expected social change. However, similar to what happens in the study of social movements, there are diverse voices and views concerning goals, expected success, and allowed

actions among protesters. Accordingly, protest events cannot be characterized as uniform entities. Thus, along with peaceful actions, protesters may also take part in protest violence (e.g., throwing stones at the police, damaging buildings) as a form of collective violence (Tilly 2003) that may be a result of either preplanned strategies or spontaneous reactions to immediate adversities (e.g., police brutality).

What Are the Main Social-Psychological Approaches to the Study of Protests?

Regarding the study of protests, the two most important types of social-psychological can and should be distinguished. The first of these approaches is concerned with the psychological *predictors* of collective action. The primary theoretical reference here is the Social Identity Model of Collective Action (SIMCA; van Zomeren 2013; van Zomeren et al. 2008) and associated theories (i.e., social identity theory and relative deprivation). In general terms, SIMCA entails four core motivations that may explain people's participation in protest: group identification, injustice/anger, group efficacy, and moral convictions (van Zomeren 2019). According to van Zomeren, these motivations are context-sensitive, and therefore, the importance of each of them would be a function of the features provided by the cultural and political systems in which people are immersed.

The second social-psychological approach is the Elaborated Social Identity Model of crowd behavior (ESIM; Drury and Reicher 2000, 2005). Unlike SIMCA, ESIM seeks to explain the *dynamics* of protests. During protests, new norms of conflict can emerge due to changes in the relationship between protesters and the police. This means that (some of those) protesters who believe that protests should be peaceful might change their views in the course of the event if police actions are experienced as illegitimate (unfair, disproportionate) and indiscriminate (nonselective use of force by police officers). As a result, protesters may become empowered (by a sense of being part of a unified crowd) to enact

new norms of conflict, to retaliate or act in self-defense against the illegitimate police action (Stott et al. 2020). This pattern has been observed at student protests, antitax protests, and environmental protests, among others (Drury and Reicher 2018). ESIM's explanation of the mechanisms through which violence may become a legitimate action has helped to dispel the myth that protest crowds are inherently violent and irrational (e.g., Le Bon 1895/2002). It has stressed instead that these conflicts are situated in a historical context where social identity (including shared definitions of legitimacy) plays a crucial role in limiting as well as enabling collective behavior. In line with ESIM, research has suggested that protesters' actions may vary (from cooperative to resistant) depending whether police officers are perceived to enable people's right to protest or to unfairly restrict the rights of protesters (Drury and Reicher 2018).

Why Does the Political Context Matter for Protests?

Like social movements, street protests do not happen in a vacuum; rather they take place in specific societal and historical settings. Even though ESIM research has considered the historical context where collective action and protest violence take place, social-psychological research has barely conducted a systematic study of both the political context in which protesters are immersed and the actors that shape this context (e.g., government officials, the police, and policymakers).

From a sociological point of view, Tilly (2008) has suggested that the occurrence of mobilization processes and the type of actions people may carry out cannot be understood without studying the political conditions under which people are living. Specifically, Tilly argues that it is not only the immediate political context that surrounds any mobilization process that scholars should look at but also the interactions people and authorities have had throughout time regarding particular claims and demands.

Regarding its occurrence, Eisinger (1973) suggested that protests are less likely to occur in

either extremely closed or highly open political systems. Conversely, street protests might be more frequent in those cities where the authorities had some degree of responsiveness to people's complaints, and the political institutions show a combination of open and closed features concerning protests. In contrast to Eisinger's ideas, Tarrow (1994) suggests that protests are more likely to occur the more tolerance a political system shows toward social mobilization processes, whereas a constrained context would make the task more difficult for protesters. With respect to performances (e.g., peaceful protests) that take place between a claimant (e.g., workers) and a target of the claims (e.g., government officials), they are shaped by the relationship those actors had maintained in the past. Furthermore, the specific actions people might carry out during a performance (e.g., protest violence) are not only historically learned but also limited for these historical interactions. This means that within a particular society, protests may be permitted activities through which people could freely complain against the government. However, what is acceptable to do during protests is restricted by law, group norms (e.g., people can march peacefully, but throwing missiles at the police is not acceptable), and a set of actions people have learned in a specific setting.

What Is the Impact of Repression on Protests?

Along with the dimensions mentioned above, another significant dimension that is part of the political context shaping the life cycle of street protests is the presence of repression (Davenport 1995, 2004; Della Porta 1995). Indeed, Della Porta (1996) argues that repression can be considered as a barometer of the political context by taking into account its direct and visible impact on social movements, and in particular, on a movement's behavior (including protests). To understand what repression is in a broader sense, Tilly provides a useful definition for it as "the cost of collective action to the contender resulting from interaction with other groups; as a process, any

action by another group which raises the contender's cost of collective actions..." (1978, p. 55).

Whereas the main perpetrator of repression against protesters is easy to identify – the police – the effects of repression on social mobilization processes are not. Thus, depending on the political circumstances under which repression takes place, its effectiveness (Davenport 2004), and the form of protest policing in each country (Della Porta and Reiter 1998), in some scenarios repression can restrict the participation of people in protests (Koopmans 1997), but in other political contexts, repression can *encourage* the engagement of citizens in protests against the establishment (Brockett 1991; Francisco 1995). To put it differently, while those who carry out repression are mostly the same almost everywhere (i.e., the police, spies), the effects of repression on mobilization processes are diverse according to the political context. Notwithstanding the latter, at the time of writing, research aimed at including protestors' perceptions of political context and the presence of repression are rare (Honari 2018a, b; Saavedra and Drury 2019b).

Should Protests Remain Peaceful All the Time?

The right to peaceful protest is included in the universal rights of freedom of expression and assembly (Howie 2018). However, Jarman and Hamilton (2009) have pointed out that restricting the right to protest to peaceful actions is problematic because it ignores the potential existence of tensions during protests and people's reasons for taking part in violent confrontations. Moreover, what counts as "peaceful" versus "violent" protest is often contested between police and protesters – as illustrated in police responses to the nonviolent direct action carried out by antiroads protesters in the 1990s (Drury and Reicher 2000). Unfortunately, some scholars have (perhaps inadvertently) contributed to the stigmatization of those who for whatever reason participate in protest violence by characterizing their actions as "non-normative," "extreme," or "radical" rather than

analyzing the process whereby forms of protest change over time (e.g., Schumpe et al. 2018; Simpson et al. 2018; Thomas and Louis 2014).

What Is the Relevance of Nonparticipants in the Study of Protests?

Evidence about what Neville and Reicher (2018) have called the "impact of crowds beyond the crowd" is rather scarce. Fortunately, this situation has started to change thanks to some recent research studies that have explored the impact of protests on both those nonparticipants that share the same proximal physical space with protesters as a university campus (Selvanathan and Lickel 2019a) and also on those who do not participate but may follow protests through mass media (e.g., Hou et al. 2018). In an interesting contribution, Selvanathan and Lickel (2019b) have suggested that nonparticipants can experience feelings of empowerment or threat in response to mass protests that may affect their identification with and support for a specific social movement. This means that rather than being passive receivers of information regarding protests, nonparticipants might actively "read" and "interpret" what it is going on in the streets. Accordingly, nonparticipants may play a crucial role in the success of protests by becoming protesters (Saab et al. 2015; Subašić et al. 2018); providing practical support for those who take to streets through financial aid, preparing food, or elaborating informative materials about protests; giving support for specific protesters' actions; or becoming sympathizers who might help protesters to gain public opinion hearts.

When Do Nonparticipants Support Protest Violence?

Just as ESIM describes how protesters' identities and definitions of legitimate practice change (Drury and Reicher 2018), recent experimental and survey research has shown that nonparticipants' support for violence can also change in a

similar way – that is, depending on the interaction between protesters and the police, as well as on the conditions set by authorities regarding protests (Lee et al. 2021; Saavedra and Drury 2019a, c). In other words, nonparticipants may support protest violence as a function of the dynamic of protests.

Moreover, recent research also suggests that nonparticipants may conceptualize protest violence as a relational phenomenon in which legitimacy may change according to the perceived context where protests take place (i.e., imposed restrictions) and who is considered the main aggressor (protesters or police officers). This idea challenges the arguments included in a plethora of psychological research which assumes that “non-violent” and “violent” actions in protests are mutually exclusive (Becker and Tausch 2015; Tausch et al. 2011; Teixeira et al. 2019), and that protest must be peaceful to ensure nonparticipants’ support (e.g., Orazani and Leidner 2019a, b; Thomas and Louis 2014). Facing a situation where the right to protest is unfairly restricted and the police attack protesters, nonparticipants may come to agree with protest violence even though they initially disagree with this type of action. This analysis helps to make sense of the growth and escalation of recent social movements, where violence became more normative but public support was also increased, such as those in Chile (2019–2020) and Hong Kong (2019–2020) (Stott et al. 2020). Consequently, we suggest that protest violence against the police (as “self-defence”) and nonparticipants’ support for these actions should be considered as a subset of protest explained in terms of their rationale instead of being marginalized and criminalized by authorities, researchers, or public opinion (Saavedra and Drury 2019a).

Media Coverage of Protests and Protest Violence

Nowadays, media coverage and new technologies (e.g., Internet) are vital sources from which people can get information about protests and those who participate in them (McGarty et al. 2014). Thus, through media outlets, people can get an idea of

public opinion regarding protests and the actions protesters carry out in the streets (Selvanathan and Lickel 2020). However, this involves three main issues. The first of these concerns the invocation of “public opinion” in media coverage. Public opinion can be depicted in different forms – through survey polls, statements by reporters and officials, or the generalization of some bystanders’ views (McLeod and Hertog 1992). The problem with many of these characterizations of public opinion is they can be inaccurate, or mere manipulations aimed at demonizing protests and protesters.

The second is the issue the approach used to frame protests. Framing of protests is related to the paradigm of protest (Chan and Lee 1984; McLeod 2007). In short, this means that media coverage may negatively affect people’s ideas (e.g., nonparticipants) by making them see protesters as outsiders (i.e., setting a division line between protesters and the whole society), and putting excessive emphasis on “radical” actions (e.g., protest violence against the police) carried out by protesters (Lee 2014).

The third critical aspect is to resist misrepresentations about protests taking into account that protest violence can appear and disappear during a single event (Day et al. 2018). Thus, protesters could alternate between different actions to confront restrictions imposed by authorities or other groups (e.g., counterprotesters). Therefore, people should point that many reports on protesters’ actions released through media outlets (e.g., use of violence against the police) may be only partial snapshots that do not necessarily represent neither the whole protest nor show the reasons protesters considered to carry out those behaviors.

Summary

In this entry, we have described a set of characteristics that allow us to recognize protest as a phenomenon worth to be studied in its own right. In particular, we distinguished between two concepts frequently used interchangeably, street protests and social movements.

This entry also shed light on the relevance that both authorities' measures regarding protests and the presence of repression (political context) have to the study of protests. Indeed, we highlighted the fact that, despite the pervasive idea that protest should be peaceful to gain legitimacy, protesters and nonparticipants' support for protest violence is often based on a similar rationale. This means that the perceived political context and the dynamic of protests (the interactions among protesters and the police) are the reference points for people's evaluations of their support (or not) for protesters' violence. Thus, protesters and nonparticipants may conceptualize pushing back or even fighting police officers as legitimate self-defense when people perceive the government trying to restrict the right to protest and police arbitrarily beating or arresting protesters. The latter means suggest that protesters and nonparticipants may conceive protest violence as situational and relational phenomena that should not be reduced to explanations based on personal traits, ideological orientations, or the irrationality and dangerousness classically attributed to crowds.

Undoubtedly, and for the sake of democracy, protests will continue to take place worldwide. Accordingly, both scholars and public opinion need to be aware of the political conditions under which these protests occur, the occurrence of protest violence, potential media coverage bias on protests, and the dynamics of protests that make people support (or oppose) protest violence. Indeed, we argue that people must focus their efforts on understanding the political trajectories and historical repertoire of protests of a specific society before analyzing and judging the occurrence of protest violence and the support it can gain from public opinion. We suggest that one of the main effects of these efforts would be that those who use (and support) protest violence will not be immediately vilified because of their actions and thoughts.

Striving

► Spirituality

Sublime

Robert R. Clewis

Gwynedd Mercy University, Gwynedd Valley, PA, USA

Abstract

This entry defines the sublime and presents its historical context, focusing on its conceptual and philosophical aspects. The sublime denotes an intense, charged emotion with high arousal and containing a mixed valence

(negative-positive). A sublime experience is an aesthetic experience of uplift and elevation in response to a powerful or vast object that is otherwise typically experienced as menacing or overwhelming. The experience is overall positive and pleasing, for participants typically desire the experience to continue. Second, this entry surveys several themes disputed in the literature: the sublime's relation to beauty, fear, and awe, why it is pleasing, and its being self-referential or reflexive. Third, the entry summarizes recent empirical research on the topic. The sublime has received relatively little scientific attention, only beginning in the past decade. A prominent empirical approach to the sublime conceptualizes it as having a fear component, although some recent studies have begun to question this. Finally, the entry concludes with a reflection on the sublime and the possible.

This entry defines the sublime and considers it in its historical and philosophical contexts. Second, it surveys several themes disputed in the literature: the sublime's relation to beauty, fear, and awe, why it is pleasing, and its being self-referential or reflexive. Third, it summarizes the empirical research in this area that has recently emerged. Finally, the entry addresses the connection between the sublime and the possible.

Definition and Philosophical History

The sublime denotes an intense, charged experience that has a high arousal and a mixed valence (negative-positive). Sometimes called an experience of “sublimity,” the sublime is an aesthetic experience of uplift and elevation in response to a powerful or vast object that otherwise is typically experienced as menacing or overwhelming. Although the valence of the experience is

generally mixed, it is overall a positive one, for participants typically desire the experience to continue.

The trigger may be natural, artifactual, or conceptual (as in a grand theory or proof). Typical examples of elicitors include waterfalls, icebergs, raging storms, deep ravines, canyons, the starry sky, mountain ranges, and striking cathedrals, dams, and ancient ruins. Here are some concrete examples from the world of art or artifact: Haydn's *Creation*, Beethoven's Ninth symphony and Wagner's *Lohengrin*; the poetry of Homer, Shakespeare, Milton, Wordsworth, Coleridge, Leopardi, Baudelaire, Edgar Allan Poe, Walt Whitman, or Nikki Giovanni; an image of a black hole or a photo of the Milky Way; the sculptures of Richard Serra; the paintings of Caspar David Friedrich, J. M. W. Turner, John Martin, and Barnett Newman; the tragedies of Sophocles or Schiller; Werner Herzog's film *Aguirre: The Wrath of God* and many scenes from natural disaster and doomsday films; St. Peter's in Rome, and the churches at Chartres, Milan, or Ulm. To say these are considered “sublime” is not to use the term as an epithet for “excellent” but is to indicate that the objects are likely or disposed to elicit a sublime response, or at least a response lying on a continuum going from chills/thrills to being moved to the sublime (Konečni 2005).

The sublime is traditionally conceived as being what is called an “aesthetic” experience. The sublime may well be connected to politics or religion or have political or religious dimensions, but in authors ranging from Longinus, Burke, Kant, and Schopenhauer, it has been seen as primarily aesthetic. An aesthetic experience is a perceptual-sensory, cognitive, and/or emotional-affective response to objects engaged with or attended to with absorbed attention. The aesthetic involves a particular kind of stance toward or interaction with the object or event, which has been understood in terms of disinterestedness and distancing (Menninghaus et al. 2017).

Philosophical discourse on the sublime can (in the Greco-Roman tradition) be traced back to the first-century CE work *On the Sublime* (*Peri Hypsous*) by an author referred to as Longinus or

pseudo-Longinus (2019). Some scholars argue that a discussion of *hypsous* goes back even to certain passages by Plato or the Pre-Socratics and Homer (Shaw 2017; Kirwan 2005; Porter 2015). In late ancient and medieval aesthetics, from Augustine to Aquinas, the experience was often connected to an experience of God or the divine. This is true even in a late Renaissance account found in Petrarch (2019), who describes his experience ascending Mount Ventoux in 1336. At the mountain summit, he reads a passage from Augustine and reflects on the triviality of ordinary affairs, admiring the greatness of the mind drawing closer to God.

The sublime came into its own as an explicit category, and distinctly aesthetic notion, in the modern period. In an influential treatise on the sublime (1757), Edmund Burke – the author probably most cited by contemporary empirical researchers studying the sublime – characterized the experience as a kind of “delight” caused by “terror” (Burke 2019). Such terror was paradigmatically induced by objects with qualities such as power, vastness, obscurity, darkness, and seeming endlessness. Burke offered detailed (though now dated) psychological and physiological descriptions of the experience. In addition, he emphasized a distinction between the sublime and the beautiful. Whereas the experience of the sublime was triggered by qualities such as ruggedness and vastness and contained an element of terror, the feeling of beauty was elicited by features such as being small, smooth, polished, light, and delicate and was simply agreeable and pleasing.

In the *Critique of the Power of Judgment* (1790), Kant presented a very influential theory of the sublime, dividing up the sublime into the mathematical and the dynamical, as responses to overwhelming vastness and power, respectively (Kant 2019). Kant described the experience as a mixed but ultimately pleasant coordination between the mental capacities of reason and imagination. For Kant, the stimulus of the sublime experience was typically a marvel of nature. For this reason, his ideas have been important for contemporary theories of the environmental sublime (Brady 2013, 2019). Although he

emphasized the natural sublime, Kant also acknowledged the possibility of feeling the sublime in response to art (Kant 2019).

While rejecting Kant’s ultimate grounding of the sublime on a human capacity for morality, Schopenhauer accepted Kant’s view that aesthetic experience required adopting a “disinterested” perspective. The sublime gave us insight into the world as it was in itself (the “world” as “will”), in which we are all part of a larger whole (Schopenhauer 2019). In order to experience the sublime, he thought, it is necessary to adopt a perspective in which private interests are downplayed or ignored, in a moment of the loss of self. Thus, the experience involved an awareness of the smallness of everyday things and even life itself. Like Burke and Kant, Schopenhauer distinguished the sublime from beauty. Unlike Kant, he viewed the sublime as being on continuum from weaker to stronger forms of intensity and arousal.

In his 1835 lectures on fine art, Hegel (2019) identified the sublime in art, above all, in the religious poetry found in the Indian, Persian, Hebrew, and Christian mystical traditions. The sublime expressed in the poetry involved a person’s recognition of his or her finite inadequacy, or insignificance, before a higher supernatural power. While Hegel discussed the sublime separately from beauty, he viewed the sublime as ultimately a mode of beauty.

Theories such as these (see Table 1) inspire contemporary accounts of the sublime.

Core Themes

Relation to Beauty, Fear, Awe

Some theorists (e.g., Hegel) see the sublime as a kind of beauty, although they grant that it is an intense kind. In any early work of 1764, Kant admits that the sublime can be combined with beauty: in the splendid or magnificent sublime, beauty is “spread over a sublime prospect” (Clewis 2019a, p. 106). This approach is also represented in the psychological literature (2005, 2011) and even in recent philosophy (Zangwill 2019). Proponents of this view cite the fact that

Sublime, Table 1 Key points in theories of the sublime

Author	Does the person feel significant and have sense of smaller self?	Does one experience a feeling of connectedness, and belonging?	Is the experience primarily sensory-perceptual, or cognitive?	Is the elicitor typically art (artifact), or nature?	Does one reflect on oneself (consciously, reflexively) during the experience?	Is the imagination activated and expanded?	Does one have a sense of freedom and detachment from the mundane?
Longinus (1st-3rd c. CE)	No, the soul appears to admire its nobility	Unclear	Can be either	Either, but typically poetry and rhetoric	Unclear	It seems so	Yes
Burke (1757)	Unclear	No, separation from the object of delightful terror	Primarily sensory-perceptual	Either nature or art (especially poetry)	No	It seems so	Unclear
Kant (1790)	No, one feels significant on account of reason Yes, one feels insignificant/smaller self (yet oneness with the world)	Yes, belonging to the moral world or order Yes, belonging to a universe or world, the one (metaphysically)	Can be either Can be either	Either, but typically nature Either nature or art (music, dramatic tragedy)	Yes (at least according to the standard interpretation) Yes, sometimes, but it is not necessary	Yes Unclear	Yes Yes
Hegel (1835)	Yes, one feels insignificant/smaller self	No, separation from the infinite (or supernatural power)	Can be either	Typically art (esp. religious poetry)	Unclear	Unclear	Unclear

the experience (while mixed) appears to be pleasant overall rather than one of terror in response to danger. In contrast, theorists such as Burke and Kant distinguish it from beauty, citing the fact that different kinds of objects appear to elicit two distinct kinds of aesthetic experiences, differentiated by their arousal or intensity as well as physiological responses (chills, goosebumps, increased heart rate). Even within the view that the sublime cannot be categorized as a kind of beauty, there are subtle disagreements. Whereas Burke's theory focuses on terror caused by danger or extremity, the Kant of 1790 (2019) and Schopenhauer both deny that the sublime contains actual fear. Unlike Burke, they maintain that the experience of the sublime is disinterested.

A Burkean view of the fear component in the sublime can be found in recent psychological research. Gordon et al. (2017) present a threat-based kind of the sublime. This approach has philosophical precedent in the theory of Burke, who holds that the sublime contains an element of terror (that is, "delightful" terror).

This issue raises the issue of the sublime's relation to "awe," which is etymologically rooted in an older Germanic-Norse word for "fear." The term "awe" was used by prominent writers on the sublime such as Burke, but they did not make it the object of their study. There is not yet consensus in either psychology or philosophy about how awe and the sublime are related to each other. There are four main perspectives on the relation.

The first approach holds that awe and the sublime are *not* related in any significant way, at least no more than other distinct aesthetic concepts might be. This is the approach adopted by most of the psychological research on awe carried out in the wake of Keltner and Haidt (2003). The *second* view is that the awe and the sublime are identical. The identity claim can be understood in extensional and intensional senses. Indeed, a great deal of recent empirical research tends to conflate the two concepts. A *third* option is the component view. There are two strands of this approach. The first strand states that awe is a component of the sublime. For instance, Bethelmy and Corraliza (2019) propose that awe is part of the "sublime experience toward nature." (The other key

component of the sublime is what they call "inspiring energy.") They propose to view the sublime as a "unifying feeling that encompasses awe and positive and pleasurable emotions within a single construct" (2019). Ishizu and Semir (2014) propose that awe and fear are components of the sublime. The second strand states the converse: the sublime is a component of awe, that is, a necessary part of the experience of awe.

The *fourth* position is that awe and the sublime overlap somewhat in extension and intension but are not identical. One version of this view is that they are in a family resemblance relation. For instance, Brady claims that awe and the sublime are "neighboring" concepts. Likewise, Keltner and Haidt (2003) call the sublime an awe-*like* aesthetic emotion (p. 299). One version of this family resemblance view is that the sublime is best seen as aesthetic awe; this implies that awe and the sublime are related and overlap. Calling the sublime an "aesthetic" kind of awe, Konečni distinguishes it from religious awe and sociopolitical awe (Konečni 2005, 2011). Conceiving of the sublime as aesthetic awe reconciles many of the apparent differences between awe and the sublime – if the sublime is only a kind of awe, the sublime cannot be identified with awe or conflated with it. It also accounts for many of the similarities and areas of overlap between awe and the sublime (mixed valence; response to vastness and consequent accommodation; feeling of transcendence; self-loss and connectedness; altered perception of time; prosocial attitudes; similar physiological responses).

One might think that whereas awe refers to a subjective state or experience, the sublime is the property of an object. This may even be suggested by the Merriam-Webster dictionary's entry for the term, "sublime": "lofty, grand, or exalted in thought, expression, or manner; of outstanding spiritual, intellectual, or moral worth; tending to inspire awe." However, many theorists view the sublime as a mental state too. In the work of Burke (2019) and Kant (2019), the sublime is understood as a subjective feeling and experience, even an emotion (*Rührung*). Wordsworth writes of "the sensation of sublimity" as "a comprehensive awe" (2019, p. 180). Using "feeling" is a

prominent way to speak of “aesthetic emotions” such as the sublime (Menninghaus et al. 2019). Keltner and Haidt (2003), as noted, refer to the sublime as an awe-like aesthetic *emotion* (p. 299) and thus did not view it as an objective property. This perspective of the sublime as a subjective state or experience is also found in a recent study of the sublime (Pelowski et al. 2019).

Why Pleasing?

There is a puzzle regarding how the experience of the sublime can be pleasant and satisfying rather than unsettling (Forsey 2007; Clewis 2019a). Why should a large or powerful object that is ordinarily overpowering or menacing, not simply upset people rather than evoke the sublime? Three answers have been given: a sense of belonging, rising above everydayness, and activated imagination.

Schopenhauer suggested that the sublime is pleasant on account of a sense of belonging or connectedness. “We are one with the world and are therefore not oppressed but exalted by its immensity” (Schopenhauer 2019, p. 197). For Kant (2019), a related sense of belonging emerges when one finds one’s place in a moral order.

Kant posited that the sublime is pleasing because it involves freedom or detachment from everyday affairs. When looked at from a distance and the greater scheme of things, ordinary endeavors seem relatively trivial during sublime experiences. “In our aesthetic judgment nature is judged as sublime not insofar as it arouses fear, but rather because it calls forth our power . . . to regard those things about which we are concerned (goods, health and life) as trivial” (Kant 2019). In the sublime, the removal of this burden is experienced with satisfaction.

Finally, several theorists think that the imagination is engaged or “expanded” in the experience of the sublime, leading to pleasure. Anna Aikin, William Wordsworth, Moses Mendelssohn, and Kant (Clewis 2019a) emphasized the role of the imagination in sublime experiences. This view is also found in contemporary theories (Hepburn 1996; Brady 2013; Clewis 2019b, p. 349).

In short, the experience of the sublime is pleasant insofar as someone finds his or her place in a

larger scheme; or because a release from troublesome burdens is itself satisfying; or because the activation of a core mental capacity brings pleasure.

Reflexivity

Some theories maintain that the sublime experience must be reflexive and concern explicitly self-directed attention. Kant (2019) and Dennis (2019) tend to be read as emphasizing that in the sublime one is thinking about oneself rather than oriented toward the external world. But when one is directing attention to oneself, does the self feel greater and more significant, or smaller and less significant?

Dennis offers what can be called an “admiration” theory of the sublime, where the mind has a “conscious view of its own excellency” (Dennis 2019, p. 62). Kant too is sometimes interpreted this way. In contrast, Schopenhauer emphasizes that the experience of the sublime involves a sense of a diminished self and self-loss (Schopenhauer 2019, p. 195).

It remains unclear how much a sense of self loss is salient to the individual or instead a result of *outward* focus on external surroundings. The degree and content of self-awareness during sublime experiences remains controversial. Moreover, the relation between self-directedness (reflexivity) and feeling of self-loss still needs to be worked out (Sundararajan 2002).

Empirical Research

Whereas the sublime has been the topic of a vast body of literature in philosophy for more than two millennia (Clewis 2019a; Porter 2015; Costelloe 2012), empirical research on the sublime has been scarce, beginning only around 2012 (Eskine et al. 2012). But it is fair to say that the sublime is now a topic of interest in psychology (Pelowski et al. 2019; Gordon et al. 2017; Bethelmy and Corraliza 2019; Van Elk et al. 2016). In a neuroscience study inspired by Burke’s distinction between the sublime and the beautiful, Ishizu and Semir (2014) examined the neural correlates of the sublime.

The relative neglect of the sublime is surprising given that awe, a closely related experience, has been intensely studied since about 2003, following a seminal article by Keltner and Haidt. Within the framework introduced by Keltner and Haidt (2003), psychological studies of awe developed in isolation from work on the sublime. But this is slowly changing, as psychologists draw close connections between awe and the sublime (e.g., Gordon et al. 2017, p. 310, p. 311; Bethelmy and Corraliza 2019; Van Elk et al. 2016, p. 11). Pelowski et al. (2019) found that the sublime is correlated with awe. Yet such claims are made mostly in passing. To date, there is little empirical study explicitly devoted to the relationship between awe and the sublime.

Most of the empirical studies of the sublime have been quantitative rather than qualitative. There is not yet a validated scale studying the sublime, leaving studies to introduce ad hoc items on the sublime.

As noted, some researchers claim that the sublime contains a fear component (Eskine et al. 2012; Ortlieb et al. 2016; Ishizu and Semir 2014). But the presence of fear in the sublime remains unclear. Recent studies cast some doubt on whether there is a strong fear component in the sublime (Hur et al. 2018; Pelowski et al. 2019). In the study by Hur et al. (2018), participants thought that they felt fear, but they did not display the typical physiological indicators of fear: participant appraisals differed from physiological responses. The latter result (absence of physiological responses associated with fear) is aligned with “disinterested” or “distancing” theories that downplay the role of fear in the sublime (Kant, Schopenhauer). Likewise, Konečni holds that the sublime can be more easily switched off than other fundamental emotions, a feature that differentiates the sublime from ordinary, uncontrollable fear (Konečni 2005). On the other hand, Gordon et al. (2017) posit a threat-based variant of the sublime, to go alongside the (more widely accepted) positive variant. Pelowski et al. (2019) likewise noticed a possible fear-based variant of the sublime, yet leave the issue open-ended as merely conjectural. Thus, it is at this point still

unclear whether this proposed subspecies of the sublime constitutes a distinct variant, or is instead a different experience altogether, a kind of fear.

How effectively the experience of the sublime can be elicited by artworks or artifacts rather than by landscape and natural scenery is currently under study. Preliminary evidence suggests that nature and natural scenery are better or more paradigmatic elicitors (Pelowski et al. 2019).

Finally, there is some reason to think that sublime experiences can be found across diverse cultures (Konečni 2005). Indeed, descriptions of similar experiences appear in traditional literary texts from around the globe, in India, China, and Japan as well as in the western traditions deriving from ancient Greece and Rome (Clewis 2019a). But the issue awaits further empirical study. While related emotions like awe and “being moved” (*kama muta*) appear to be cross-cultural (Razavi et al. 2016; Zickfeld et al. 2019), the extent to which experiences of the sublime are cross-cultural has only initially been studied using empirical methods (Pelowski et al. 2019).

The Sublime and the Possible

The sublime can be connected to the possible by way of the imagination. As we have seen, several theorists such as Kant (2019) highlight the activation and expansion of the imagination during the sublime. The imagination has been conceived as the ability to represent or conceive what is possible rather than actual (Gendler and Hawthorne 2002; Yablo 1993; Kung 2010). It is the mental capacity for thinking about the possible and what is not present. It thus refers to thinking about many different possibilities, both present and future. This aspect has not been investigated much by psychology studies of the sublime.

To conclude, the intense, mixed aesthetic experience of the sublime has a long and venerable history in philosophy, rhetoric, and literary studies. It is now being more and more studied in empirical fields, using quantitative and qualitative methods.

Surprise

Wendy Ross¹ and Margaret Webb²

¹Department of Psychology, London Metropolitan University, London, UK

²University of Melbourne, Melbourne, VIC, Australia

Abstract

An unexpected or inexplicable event with significance to the self that is accompanied by a strong emotional marker (which can be positive, negative, or mixed in valence).

Keywords

Surprise · Insight · Serendipity · Error

Surprise and the Possibility Space

Possibility refers to that which is not actual. It invites us to consider “what could be,” “what is to come,” “what could have been,” and “what is not / will never be.” In interaction with the world (sometimes only our internal world), possibilities can lead us to “what was unexpected.” These unexpected events, when they are of subjective significance, are marked by the epistemic emotion of surprise.

We can all recognize the feeling of surprise, typically when we encounter something unexpected but which we instinctively believe even if we are curious about its origins. Take for example, the serendipitous surprise of bumping into a dear friend in a country that you did not expect them to be in. A further surprising event, to take a more thoroughly researched example, might be scientists receiving reports of unexpected side effects of drugs which indicate new unanticipated ways that the drug works on the body (Rocca et al. 2019). These reports are not expected, but they trigger curiosity and exploration. Surprise can be not only a marker of this expected violation, but also a marker of unexpected understanding (insight). In the case of the latter, surprise marks both the recognition of prior ignorance and the discovery of new knowledge.

Beyond these broad phenomena such as serendipity, insight, and creativity, surprise underpins and explains aspects of human cognition across several different levels and, we will argue, is fundamental to understanding how we interact with the unpredictable and unexpected nature of the possible (Glăveanu 2021). We go further to suggest that increased attention to the role of surprise in thinking and behavior can support our understanding of how cognition unfolds in the face of uncertainty, allowing us to flesh out and adjudicate between different models at different cognitive levels. In this respect, it is “surprising” that this complex phenomenon has often been relegated to a minor role (Nevo and Erev 2012). We shall end by considering the importance of surprise to the complex interactional process of serendipity and suggest that the importance of unplanned discoveries in human discovery requires us to understand surprise as more than an epiphenomenon of otherwise clear processes.

Levels of Surprise

At a cognitive and neural level, surprise is theorized to underpin many of the most fundamental components of learning and memory (Alexander and Brown 2019). It has been posited as a meta-cognitive signal to update mental models to incorporate new, unexpected information (Munnich and Ranney 2019). At the affective level, surprise

is accompanied by reliable phenomenological markers that can be positively or negatively valenced. As a basic human emotion (Ekman 1992), surprise is universally recognizable, though inherently relational and idiosyncratic.

At the neural-computational level, the term by which surprise is theorized as fundamental to human cognition is *prediction error* (Schultz et al. 1997). Prediction error is the difference between the expected event and the outcome. If there is a discrepancy, then a prediction error occurs and flags requirements for learning. For example, if the prediction is of business as usual, and a change occurs (for example, an “appetitive event,” perhaps a shot of melted chocolate for humans such as these authors), dopaminergic neurons fire. If there is a consistent stimulus that can predict the shot of melted chocolate (for example, a particular sound), then the sound itself (if unexpected) can trigger the dopamine response (with the response having shifted through *error correction* from the reaction to the shot of melted chocolate to the sound). If the sound is made and no shot of melted chocolate is forthcoming, there is a decrease in firing of dopaminergic neurons. This variation in firing of dopamine is proposed to provide the basis of learning and conflict detection (Alexander and Brown 2019), which themselves underlie a vast array of other cognitive processes. Surprise as prediction error is a highly robust finding and has been used to model (as noted above) many and varied cognitive processes.

Nevertheless, how the feeling of surprise enters *awareness* is unclear. We do not stroll through the world constantly surprised that our predictions are correct or incorrect; we learn through the difference between predicted and actual interactions with the world, but each interaction is not overwhelmingly memorable (Fazio and Marsh 2009). Yet moments of surprise *are* memorable and often accompanied by a strong affective component (Ekman and Friesen 1971; Reisenzein and Studtmann 2007). Some models (such as the Alexander and Brown model noted above) propose multiple levels of error detection. In this case, it may be that sufficiently high levels of error detection also trigger the feeling of surprise as we know it, as well as sufficiently high

levels of activation for consciously linking that feeling with the surprising event. It may also be that different magnitudes of prediction error (across multiple circuits) could offer an explanation (Hélie and Sun 2010) in their model of insight, and propose a similar mechanism by which an insight is reached. In either case, it may be that surprise can indicate the point at which relying on an unconscious updating of the current knowledge state surpasses tolerable bounds.

Surprise as a feeling is therefore an important component of what motivates an individual to explore the world and knowledge space. As Clarke (2018, p. 521) suggests: “We humans often seem to actively seek out surprising events, deliberately harvesting novel and exciting streams of sensory stimulation.” This perspective points not only to the importance of surprise in human cognition and behavior but also to our role in generating it through epistemic “foraging.” In this way, rather than casting the human as a passive recipient of the surprising moment, surprise can be seen as part of a process of the flow of actions and events. It is something we actively create through continual explorative action (Austin 1979). In short, surprise in all its forms marks the experience of prodding at an unpredictable world.

Theories of prediction error and surprisal underlie the proposal of active inference (for a recent overview, see Friston et al. 2017), a view of cognition which is increasing in popularity (Hohwy 2013). This theory proposes that cognition is motivated by a desire to minimize prediction error by reducing uncertainty. While surprise is inevitable in an uncertain world, a strict approach to prediction error minimization proposes that an organism will seek to *minimize* surprise through actions which decrease the difference between mental models and the external stimuli, and minimize surprisal in all its forms. There is no clear motivation to increase prediction error because this is cognitively inefficient. We see that we have to account for this *desire* for phenomenological surprise as well as cataloguing moments of neural surprisal. The novelty-seeking nature of phenomena such as creativity then

becomes essential for such models to explain (to avoid the so-called Darkened Room scenario by which an agent ends up in the most predictable environment – a dark room; see Gallagher in prep). Clark (2018) addresses the role of surprise seeking in theories of active inference and ends up accounting for it by recognizing the importance of complex social and cultural environments, what he calls “exotic statistical baths” (p. 532). These environmental structures scaffold epistemic foraging rather than it being something which can be explained by a purely internal model. Ultimately, then the feeling of surprise and its metacognitive and epistemic function cannot be accounted for on a neural level alone and requires us to understand cognition as affective and extended.

The Epistemic Role of Surprise

Surprise refers to a feeling of sharp, sudden, and unexpected expansion of the possibility space. Importantly, this expansion is one which results in an updating of the current knowledge state rather than a rejection of the intrusion (Steinbock 2018). Expressing surprise is not the same as expressing skepticism; we are surprised by something which is evidentially true but which we have not considered before. This is clearly illustrated when we say “That would surprise me if it *were* true” where the level of surprise is related to the truth of the object. We are not surprised by something we do not believe; surprise requires us to grant the truth of the proposition which surprises us. It is this rapid recognition of new knowledge that accompanies the confidence of an insight experience. Surprise is therefore epistemically important: an epistemic feeling.

Epistemic feelings are those feelings which motivate the exploration of the world and knowledge space (Arango-Muñoz and Michaelian 2014). They are elements of the emotional spectrum closely connected to knowledge and knowledge exploration. However, surprise differs from most epistemic feelings because it is initially not directed toward action rather it is in a reaction to actions and events. However, while it is complete

in itself, it is not a short-lived phenomenon with no additional effects. The updating of the knowledge base requires action to incorporate this new knowledge which leads to exploratory feelings such as curiosity and wonder. Johnson-laird and Oatley (1992) argue that Ekman’s basic emotions each serve an important function. In the case of surprise, we suggest the feeling of surprise serves a metacognitive function, that of forcing a reorientation of epistemic activity. It is the cessation and disruption of the existing expectations which marks the threshold into consciousness. Therefore, while surprise has an epistemic element, it is a moment not of exploration (epistemic or otherwise) but rather one of stopping of action and diverting attention.

Importantly, the new knowledge marked by the feeling of surprise comes from the process of interacting with the world (Glăveanu [forthcoming](#)) lending weight to arguments that engagement is important in understanding creativity and innovation. Surprise marks the moment when external stimuli challenge internal stability; it is impossible to be surprised by something of which you are already aware (although you may become surprised by an unanticipated perspective). Instead, surprise marks a moment when the world comes into a novel focus and a person’s perspective on that world changes. It is an epistemic judgment related to prior expectations and the likelihood of an event. It brings into focus the unexpectedness of being in the world and also destabilizes ideas of unrestrained human agency and the imposition of that agency on inert material. In this way, surprise marks the realization that what could be is wildly different from what is. It is, thus, the epistemic feeling most closely associated with the unanticipated possible.

Additionally, this requirement for interaction undergirding the feeling of surprise reminds us of the distributed nature of knowledge. The feeling of surprise is a marker of the moment of incongruence between external stimuli and a mental plan or perspective forcing it to be updated. As Gerlain (2019) notes, it reminds us of an implicit world outside the world of our current experience. When it comes to the relationship between surprise and the possible, surprise marks the moment

when the unexpected, unconsidered, and seemingly impossible are recognized as possible and supports the disambiguation of the possible from the merely probable.

Surprise as a Necessary Component of Insight

Moments of insight are universally recognized as instances of realization in which feelings of sudden confidence arise for an answer. This answer may have been actively searched for (e.g., when trying to solve an ill-defined problem in computer programming), or not actively searched for (e.g., realizing the unsought solution to an issue while showering). The definitional components of the feeling, whether accompanied by pleasure or dismay, are that of *sudden confidence* (Cushen and Wiley 2012). Moments of insight provide a disjunct between the previous representation of the problem and the current representation of the problem, with no conscious memory of the problem-solving pathway between the two.

The feeling accompanying moments of insight, that of surprising certainty in a solution, is remarkably difficult to elicit on a reliable basis, partly because, as noted above, surprise is relational. The feeling of insight is generally termed an “aha moment” in the relevant field: This is the feeling of sudden confidence in the answer (see Insight, this volume). Danek et al. (2014) identified several aspects of the feeling of insight phenomenology of which surprise was the second strongest. This confirmed previous theorizing that placed surprise as a key marker of the insight experience. For example, Gick and Lockhart (1995) suggest that the transition to a solution state which marks the moment of insight is marked by surprise that the representation required to solve the problem is different to the one held in mind by the problem solver. Surprise is also closely related to insight radicality (Jarman 2014), that is, the difference between the previous (unhelpful) problem representation and the novel one. Jarman found that increased radicality predicted the intensity of the insight experience leading us to suggest increased surprise is key to the experience.

Despite being a cornerstone in the phenomenon of insight (as a sudden and untraceable moment of realization that the original

representation of a problem was incorrect), surprise is rarely investigated as an emotional component of problem solving. However, it could be that it provides an indication of the underlying cognitive processes. There is some debate about what the cognitive processes are that underlie insight. In brief, the question is whether insightful problem solving relies on a particular special process or whether it comes from the unconscious application of the same processes which underlie all cognition (Gilhooly et al. 2015). Although it seems likely that the answer relies on a mix of both, it could be that surprise indicates which is most dominant at any one time.

In order to solve a problem with insight, a problem solver must have an unpredicted shift in understanding. The nature of this shift is currently unclear – does it represent a shift in the problem representation or a shift in the understanding of the way to solve the problem. In this way, surprise is obviously critical to theories which propose sudden representational change and non-monotonic problem solving (Danek 2018) because it marks a sharp change in the representation from previous iterations. In contrast, current theories of incremental progress (such as outlined by MacGregor et al. 2001) fail to address the feeling of surprise, but it may be that surprise in this model occurs at a different point, that is, the point at which the problem solver realizes that the approach they were using to solve the problem will not work, so-called criterion failure. In this case, surprise is not generated by the solution but by the moment that it becomes apparent that the confidence in the previous solution attempt is misplaced. A fuller appreciation of the epistemic role of surprise could scaffold further attempts to adjudicate between the two theories.

Surprise as a Threshold Marker: The Case of Serendipity

We have all had moments of serendipity – a moment of good fortune which seems completely suited to us. Serendipity refers to the interaction of an accident and the personal “sagacity” to exploit that accident. The etymological roots of accident imply something entering from outside the system. It comes from the Latin *accidere* meaning “to

fall down, impinge on, be heard, happen” (Merriam-Webster), and serendipity is firmly tied to the “act of noticing” (Rubin et al. 2011). At the heart of the notion of a serendipitous accident is that it comes from outside the existing cognitive system, involves a disruption, and that this disruption is significant enough to be noticed. These aspects can be collapsed into one: A serendipitous accident is surprising. In this way, much like for insight, surprise is at the heart of the moment of serendipity.

As with insight, surprise also gives us an interesting perspective on the mechanisms which may underlie serendipitous cognition. In this case, we are returned to the notion of a threshold which is marked by the feeling of surprise. Serendipity is a disruptive phenomenon requiring the agent to turn away from one path to follow another prompted by something unexpected. Serendipity is necessarily sparked by an accident (Makri and Blandford 2012; McCay-Peet and Toms 2015; Merton and Barber 2004). However, human activity takes place against a continual flow of accidents so the occurrence of an accident cannot be enough to spark the sense of serendipity, rather an accident is something which acts as a “game changer” (Arfini et al. 2018), and it is this which requires the element of surprise. It is not yet clear what makes an accident become important enough to be selected and enacted (see Ross, 2022), but it may be an investigation into the nature of surprise can lend support to attempt to understand these complexities.

In other words, because serendipity is something which is consciously experienced, the accident must be noticed consciously and assessed as interesting enough to be exploited. Models of surprise as a metacognitive signal can give us information on how that assessment takes place. Take, for example, the model proposed by Munnich and Ranney (2019): They offer three responses to learning new surprising information: accommodating it, treating it as an anomaly, and rejecting it. Each of these consists of three aspects – the existing belief network, the event, and the action which is undertaken. We reject an idea when it is too difficult to explain within the

context of our own belief network. As Arfini et al. (2018, p. 5) write:

Fleming’s “Oh!” reaction was when he managed to frame and understand the antibiotic effect of a mold. He did not enter his laboratory to find a moldy culture singing the chorus of Mamma mia!: that would have sparked another kind of reaction.

Things which are too distant from our belief network, where the radicality is too great, are not drawn upon to update it. The same is true of serendipitous accidents; those which fall outside the realm of what we see as possible are not followed up.

Similarly, there is a resource cost to exploiting accidents, and option D in the model encompasses the idea that an interesting anomaly is noticed, but it is not considered interesting enough to invest the time and cost. Barber and Fox (1958) tell the story of two scientists who are surprised by the same thing, but one has the resources and time to follow it up and the other does not. The realization that surprise-driven curiosity has a cost is crucial to understanding why some accidents are exploited and others are not.

In other words, serendipitous surprise relies on the event being sufficiently close to what the system views as possible; even if the knowledge is not there before, it requires the deviation from an existing theory rather than uncontextualized knowledge (Yaqub 2018). This is because serendipity requires the enacting of the unplanned event, and the boundaries of the system must be flexible and dynamic in order to assimilate this new knowledge. This is a quasi-liminal knowledge state which requires both expertise (to recognize and assimilate) and ignorance (to experience surprise). An explanation for the role of serendipity could be related to the threshold required to experience surprise.

Surprise and The Possible

As we noted in our opening paragraph, possibility refers to that which is not actual. Part of the difficulty in conceptualizing the use of other possible worlds is that those worlds are often rooted in our existing experiences. Possibility thinking is

best conceived of as a process, a continuous redefining and moving forward through adjacent possibilities to generate novel possibilities. Surprise provides an emotional identifier of when the possible has become internally actualized, as a marker of how we can interact with hitherto unanticipated domains: the marker of the actualized and expanded possible.

Surrealism

Lisa Lipinski
Columbian College of Arts and Sciences, George Washington University, Washington, DC, USA

Abstract

Surrealism, an intellectual and artistic movement, that originated in Paris before attracting followers around the world, was envisioned as a means of knowledge about oneself through the unconscious, the marvelous, the dream, and the simulation of hallucinatory states of mind. Surrealism was defined as “pure, psychic automatism” by the French poet and critic André Breton (1896–1966) in *The Manifesto of*

Surrealism (1924). Automatic techniques were devised in writing, drawing, painting, and even photography as a way to bypass rational control and subvert bourgeois social conventions, in order to foster creativity and empower the possibility of new thought and actions consistent with new values. Following a summary of the state of research on Surrealism, this entry will review the founding principles of Surrealism, and trace a brief history of Surrealist art and theory as it relates to the possible.

Research on Surrealism

Maurice Nadeau’s *History of Surrealism*, first published in French in 1944 and in English in 1965, is a classic account of the complex movement, tracing its evolution from Dada through the various phases up to the start of World War II, and includes manifestoes and documents (Nadeau 1989). In her overview of Surrealism, Anna Balakian focused on the poets of the movement, Breton, Aragon, Éluard, and Reverdy, placing them in the context of early twentieth-century Paris (Balakian 1986). The literary scholar Mary Ann Caws has written on Surrealist poetry (Caws 1970), compiled an anthology of writings, and has written on the significant contribution by women artists (Caws 1995). Marcel Jean wrote the first comprehensive book on Surrealist painting, from its precursors to the present day (Jean and Mezei 1960). Rubin’s *Dada and Surrealist Art* is a classic text with an extensive chronology of events, publications, and activities (Rubin 1968). Gérard Durozoi provides the most comprehensive history of the Surrealist movement, starting with its origins in the 1920s to its decline in the 1950s and 1960s. The book is well-illustrated with color images and a vast amount of documentary and visual evidence related to all facets of the

movement, from literature and philosophy to painting, photography, and film. *History of Surrealism* includes biographies of the major and minor figures of the movement as well as a comprehensive bibliography of Surrealism, divided into sections related to theme, specialized studies, exhibitions, and geographical areas. Susan Laxton demonstrates the importance of play in the surrealist methods and explorations into the nature of subjectivity (Laxton 2019) (see entry ► “Play”).

Anthologies of Surrealist writings provide primary sources for further study: *The Surrealism Reader: An Anthology of Ideas* (Ades et al. 2015), André Breton’s *Manifestoes* (Breton 1972) and *What is Surrealism?* (Breton 1978), and Georges Bataille’s *Visions of Excess, Selected Writings* (Bataille 1985).

Surrealist exhibitions were essential to the ideology and expression of the movement in its time and are briefly discussed at the end of the essay. Recent exhibitions provide new insights into the importance and legacy of Surrealism and are equally valuable sources of information about neglected artists. *L’Amour fou: Photography and Surrealism* examined the erotic, disorienting, and exquisite photographs produced by the Surrealists, showing the crucial role photography played in the movement. *Anxious Visions: Surrealist Art*, a ground-breaking study, considered the visual arts of surrealism in the historical climate of the interwar period (Stich 1990). The Surrealists produced a wide range of disturbing imagery which drew on their collective interests in the machine and modernity, non-Western cultures and tribal art, and contemporary politics and the rise of fascism. *Surrealism: Desire Unbound* explored the Surrealists’ vision of love, desire, sexuality, and liberty in surrealist art in words and images (Mundy et al. 2001). The catalogue featured essays by leading scholars of Surrealism. A recent exhibition, *Angels of Anarchy: Women Artists and Surrealism* explored the contribution of women artists to Surrealism (Allmer et al. 2009). The exhibition *Monsters and Myths: Surrealism & War in the 1930s and 1940s* examined Surrealist masterworks of the 1930s and 1940s by artists such as Salvador Dalí, Joan Miró, Max Ernst, and

André Masson, and presented the movement through the lens of war, violence, and exile (Shell et al. 2018).

Surrealist Art and Theory

Surrealism emerged in 1924 after a 5-year gestation period as a response to World War I and the crisis in Western culture that followed it. For the Surrealists, the experience of chaos and disorder, irrationality, and destruction of 4 years of total and devastating war, challenged and undermined traditional values of reason, logic, faith in God, and allegiance to the nation state. In place of the valorization of binary oppositions, Surrealism celebrated difference and cultivated the conjunction of different things and realities, taking inspiration from the Comte de Lautréamont’s famous line “...[beautiful as] the chance juxtaposition of a sewing machine and an umbrella on a dissecting table!” (de Lautréamont, *The Songs of Maldoror*; Canto VI, verse 3). In “Beyond Painting,” (1936) Max Ernst described the surreal as “the coupling of two realities, irreconcilable in appearance, upon a plane which apparently does not suit them” (Ernst 1948, p. 13). In *The First Manifesto of Surrealism*, French poet and visual artist André Breton wrote: “I believe in the future resolution of these two states, dream and reality, which are seemingly so contradictory, into a kind of absolute reality, a surreality, if one may so speak” (Breton, p. 14). From 1924 to 1966, new methods of art production were devised by artists and writers to bypass rational thought and traditional aesthetics. As a broad, collective, and multidisciplinary movement Surrealism opened up new possibilities of thought which the surrealists hoped would incite a social and political revolution.

On 11 October 1924, the Bureau of Surrealist Research opened in Paris with the express purpose of gathering information, using all possible methods of experimentation which would express the unconscious activity of the mind. The solicitation to the general public was open-ended and not prescriptive. The surrealists were looking for new ideas and, most notably, dreams, on which to initiate their revolution. Surrealism would be a collective endeavor, not focused solely on the production

of art or literature, but on creating a new way of being in the world, starting with automatism. Inspired by the kind of automatic writing practiced by spiritualists, the practitioners of automatism would fall into a self-induced trance in which they would write, draw, or answer questions, outside the usual constraints of logic and reason. *Cadavre exquis* (exquisite corpse) was a collaborative drawing or writing approach used by the surrealists to create bizarre and intuitive images. The results were often published in Surrealist journals (see entries ► “[Dreams](#)” and ► “[Consciousness](#)”).

The First Manifesto of Surrealism, written by André Breton (1896–1966), began with the observation that “absolute rationalism...is still in vogue” and the excessive attention to facts came at the expense of the imagination. He wrote: “The imagination is perhaps on the point of reasserting itself, of reclaiming its rights” (Breton, *Manifesto*, p. 10). He praised Sigmund Freud for his contributions to understanding psychological forces at work in shaping human behavior and social interactions, and the importance of dreams (see entry ► “[The Possible in the Life and Works of Sigmund Freud](#)”). In the *First Manifesto of Surrealism*, André Breton defined this new movement:

SURREALISM, n. Pure psychic automatism, by which it is intended to express, either verbally, or in writing, or in any other way, the true functioning of thought. Thought expressed in the absence of any control exerted by reason, and outside all moral and aesthetic considerations. *ENCYCLOPAEDIA. Philosophy.* Surrealism rests on the belief in the superior reality of certain forms of association hitherto neglected, in the omnipotence of the dream, and in the disinterested play of thought. It tends to ruin, once and for all, all other psychic mechanisms and to substitute itself for them in solving all the principle problems of life (Breton 1972, p. 26).

In “Une Vague de rêves” (A Wave of Dreams, 1924), an important historical and theoretical text on Surrealism, the French writer Louis Aragon (1897–1982), one of the three founding members of Surrealism, along with Breton and Philippe Soupault, emphasized the importance of chance, illusion, the fantastic, and dreams. He described how the

surrealists made contact with the unconscious, producing images which became perceptible as long as one was in touch with the hallucinatory phenomena. “In the grip of a tremendous momentum, we spent more and more time on the practices which led us into our strange inner lands. We delighted in observing the curve of our own exhaustion, and the derangement which followed. For then the marvelous would appear” (Aragon 1924, p. 100).

Everything is possible in the dream, which is the vivid manifestation of unconscious thoughts. The *Manifesto* provided an outline of the goals and aspirations of Surrealism – to liberate humanity and expand the realm of thought beyond the immediate and sensate reality. The Surrealists published journals devoted to their experimentations and as a means of disseminating ideas and theories, starting with *La Révolution surréaliste*, which was published from 1924 until 1929, which included descriptions of dreams, automatic texts, poems by Paul Éluard and Robert Desnos, drawings, and photographs. *La Révolution surréaliste* was modeled on the conservative scientific journal *La Nature*, which provided the surrealist journal with an appearance of objectivity and evidence of research, which demonstrated the serious nature of their ambitions and goals. Throughout the vital years of the movement, periodicals spread the word on Surrealism, taking different formats, but all featured art, photography, and writing, including: *Le Surréalisme au service de la révolution* (1930–1933), *Minotaure* (1933–1939), *VVV* (1942–1944), *View* (1940–1947), and *Documents*, a Surrealist magazine edited by Georges Bataille, published in Paris from 1929 through 1930, which ran for 15 issues.

Surrealism quickly attracted visual artists to the movement, leading Breton to consider whether oil painting, with its slow and often laborious process, was capable of capturing the dream or tapping the unconscious. Breton’s essay “Surrealism and Painting” addressed the question of whether the plastic arts could be considered surrealist. He selected the painting of Pablo Picasso as a model, for the latter’s rejection of mimetic representation in the development of Cubist painting and the new medium of collage. Picasso

showed that an artist could liberate painting from traditional forms and create a new vision of the world.

Visual artists employed automatic methods as a way of extending what was possible in art, producing widely varying styles. The German painter, printmaker, and sculptor, Max Ernst (1891–1976) explored automatic methods of creating an image, in 1925, with a series of 34 *frottage* drawings, which he assembled as a group and exhibited with the title, *Histoire naturelle*. He made rubbings of wood and other objects, transposed the rubbings to canvas, thereby inventing a new mental process of creating hypnagogic visions. Between 1921 and 1924, he produced a series of paintings evoking the irrational qualities of dreams, drawing on incidents and images from his childhood. He was endlessly inventive in creating new forms through techniques like *frottage* but also abstracting objects appropriated from mass-produced volumes, like newspapers, journals, and ethnographic publications. In 1929, he composed a “novel” in collage, *La Femme 100 têtes* (“The woman with 100 heads” or, as a pun, “the woman with no head”) which consisted of 124 captioned pictures laid out in a nonlinear and illogical sequence of evocative and ambiguous images. He created the novel by adopting images from late nineteenth-century illustrated magazines and pasting them together, thus bringing two different realities into the same pictorial space. In his collages, Ernst abstracted figurative elements from their original context to create new forms, in which the familiar became strange and fantastic. Later in his career, he experimented with new automatist techniques, inviting the element of chance into the creative process. For example, he dripped paint from a can that he swung over the canvas. Spanish painter and sculptor, Oscar Domínguez (1906–1957) joined the Surrealists in 1935. He invented a technique called decalcomania, which involved the blotting of a gouache drawing, by pressing paper against the original drawing, turning it into an ambiguously suggestive image. Ernst also employed the technique, rubbing one canvas against another covered with oil paint, which he

used to create otherworldly landscapes and dream-like images (see entry ► “[Arts Education](#)”).

André Masson (1896–1987), French painter, draughtsman, printmaker, and stage designer, whose automatic drawings were made quickly and without forethought or rational control caught the attention of Breton who invited him to join the group. Masson took this technique a step further into painting, when he sprinkled colored sands on canvas, which adhered to the automatically drawn lines of glue. In *Battle of Fishes*, 1926, (Fig. 1) poetic images emerged as if by magic from the suggestive and unpremeditated forms taken by the texture and materials of the sand paintings, offering a close visual counterpart to automatic writing. Joan Miró (1893–1983), Spanish painter, sculptor, printmaker, and decorative artist never officially joined the Surrealist movement, claimed by Breton nonetheless, his paintings of fantastic imagery of biomorphic forms and linear elements were wholly original, inventive, and mostly abstract. He devised a rich system of graphic notations, words, figures, drawn from memories of his childhood, sometimes based on hallucinations, often beginning with hastily drawn sketches which he worked into paintings. The French painter Yves Tanguy (1900–1955), a self-taught artist, joined the Surrealists in 1925, devised his own technique and style. Working with a diluted form of oil painting, he layered amorphous shapes on atmospheric backgrounds, later adding shadows to create otherworldly scenes populated by abstract forms and figures. Tanguy influenced a younger generation of Surrealists who adapted automatism into their own styles: Wolfgang Paalen, Roberto Matta, Gordon Onslow-Ford, Esteban Francés.

An autonomous Surrealist group formed in Belgium in 1925, with René Magritte (1898–1967), the sole painter in the group, at its center. Magritte approached painting as a philosophical and poetic art. He employed an illusionistic style to create the mystery of dream-like images out of ordinary objects. He developed his own methods, seeking to discover hidden affinities between things by altering their substance, scale, or spatial arrangements. He explored the relationship of

words and images, contributing an important pictorial essay, "Les mots et les images" to the final issue of *La Révolution surréaliste* in 1929.

The Spanish Catalan painter, writer, and filmmaker, Salvador Dalí (1904–1989) developed what he called the "paranoiac-critical method" to create hallucinatory dream worlds in paintings filled with his own auto-erotic symbols. The method involves a kind of controlled delusion through which one sees resemblances between disparate things (see entry ► "[Illusion in Art](#)"). Many of his works contain his famous double images, that is "a representation of an object that it is also, without the slightest physical or anatomical change, the representation of another entirely different object, the second representation being equally devoid of any deformation or abnormality betraying arrangement" (Caws 2001, p. 180) (Fig. 2). In *Swans Reflecting Elephants*, 1937, (Fig. 2) three graceful swans float on a placid pool above the reflections of three different creatures –

elephants. The necks of the swans become the trunks of the elephants below them. According to Sigmund Freud, dreams reveal our repressed or hidden desires, unfulfilled wishes. The paranoiac-critical method was a means of destabilizing the world and creating the possibility of seeing things as new or potentially something else.

From the 1930s onward, as the movement expanded its geographical scope, Surrealism attracted a significant number of women, who were often in relationships with the male artists and writers, frequently serving as model or muse. Surrealism offered women the freedom to explore issues related to their own identity and sexuality, whether or not they officially joined the movement. In the literary and visual arts, women delved into their own unconscious and dreams, producing works in which the female body expressed a unique and inimitable psychic power and creative energy. Leonor Fini (1908–1996), French painter, stage designer, and illustrator of Argentine birth,

painted sphinx-like women and female nudes in a meticulous illusionistic style. The Spanish painter Remedios Varo (1908–1963) created hybrid creatures like the human-owl figure in *Creation of the Birds*, 1957, (Fig. 3) who sits at a table drawing birds which take wing upon creation. She is surrounded by magical and fantastical beings as well as the instruments of her alchemical art. Claude Cahun (1894–1954), French photographer, writer, and sculptor, changed her name in 1917 from Lucy Schwob. Cahun explored the fluidity of gender in photographs of herself performing different character roles, a weight-lifter, aviator, dandy, and doll. Leonora Carrington (1917–2011), Mexican painter, sculptor, and writer of English birth, developed an illusionistic Surrealism based on autobiographical and occult symbolism with fantastic creatures in bizarre settings. The English painter Eileen Agar (1899–1991) experimented with automatic techniques and new materials, making collages and objects, which were included in Surrealist exhibitions. Agar described her approach in terms of the ludic: “To play is to yield oneself to a kind of magic, and to give the lie to the inconvenient

world of fact, and the hideous edifice of unrelieved utility. In play the mind is prepared to accept the unimagined and incredible, to enter a world where different laws apply, to be free, unfettered” (Caws, p. 4–5). Mythic female figures, like the nymph, the witch, the fairy, the crone, whose powers derive from their mutability – appear frequently in paintings by Carrington, Fini, and Dorothea Tanning (see entry ► “Myths”). All of the Surrealists were obsessed with metamorphosis and latent eroticism; the women developed their own eccentric creatures and iconography which was equally, if not more, memorable, disruptive, and haunting (see entry ► “Imagery”). The American painter, sculptor, illustrator, stage designer, and writer Dorothea Tanning (1910–2012) was inspired to become a painter after she saw the exhibition *Fantastic, Art, Dada, Surrealism* at the Museum of Modern Art, New York, in 1936. Tanning’s first surrealist painting *Birthday*, 1942 (Fig. 4) features a half-nude figure, a self-portrait, clad in a dress whose skirt is composed of writing green bodies. Beside her is a fantastic furry creature, her familiar. The open door reveals a succession of open doors which lead the viewer’s gaze

into the ambiguous depths of the canvas, serving as a metaphor for the unconscious or the imagination. The mirror behind the figure further complicates the pictorial space. “I wanted to lead the eye into spaces that hid, revealed, and transformed all at once and where there would be some never-before-seen images, as if it had appeared with no help from me,” she wrote (Tanning 2001, p. 214). Her future husband, Max Ernst, saw the painting and gave it the title, *Birthday*.

In March 1930 an exhibition of collages was held at the Galerie Goemans in Paris. Louis Aragon wrote an essay for the catalogue, “La Peinture au défi” (The Challenge of Painting), in which he revived the concept of the marvelous as a “dialectical event” and a means of liberation (Éluard and Hultén 1990). He offered this hypothesis: “the rapport born of the negation of the real by the marvelous is essentially ethical in character, and the marvelous is always the materialization of a moral symbol in violent opposition to the morals of the world in which it surges forth” (Aragon, in Pontus Hultén 1990, p. 48). According to Aragon, collage was a “poor” medium in contrast to painting, because it did not require technical skills and it was made of inexpensive, found materials. The

avant-garde medium of collage offered Surrealism a new method of composition, specifically, the act of bringing disparate things together, thereby producing disjunctive and unexpected results.

Beyond the visual arts, the surrealists conducted experiments in shared or collective writing. *L'Immaculée Conception*, (The Immaculate Conception) a poem co-written by Breton and Paul Éluard, with an illustration by Dalí, offers a model of an anti-hierarchical method, one which transcended the individual and his/her preferences for a more egalitarian and collective practice. In his preface to the Japanese translation of *L'Immaculée Conception*, Éluard wrote: "To be two to destroy, to build, to live, is already to be everyone, to be the other to infinity and no longer oneself. . . A thoughtful and thorough examination of the possibilities of thought. . . of thought which is common to all, renders vain any hierarchy among men. Between man and woman, it would be the very negation of their own roles" (Durozoi 2009, p. 196) (see entry ► "Poetry").

Objective chance was another surrealist method used to tap into the unconscious. Breton and others frequently visited flea markets, hoping to find objects which offered the possibility of expressing inner desires. In 1934, Breton found such an object at the Puces de Saint-Ouen flea market in Paris – a long, rounded wooden ladle with a shoe shape carved into the base of its handle. For days before this outing, he had the phrase "le cendrier de Cendrillon" (Cinderella's ash tray) running through his mind. The tiny shoe at the base of the spoon's handle suddenly revealed its meaning. Man Ray photographed the found object, which Breton called the "slipper spoon," thus revealing the latent and powerful connection between an object found by chance and the unconscious thoughts of the poet.

The Surrealists explored themes of desire and love with humor and passion, making works which challenged strict censorship laws in France, the influence of the Catholic Church, legal and social inequalities, the political and ethical dilemmas posed by the rise of fascism and communism. In 1929, the final issue of *La Révolution surréaliste* posed a question to the

public: "what sort of hope do you place in love?" Paul Éluard's volume of poetry *Facile* (1935) consisted of lyrical evocations of his lover juxtaposed with Man Ray's photographs of the nude body of Nusch, his companion at the time. Breton's second book, *Nadja*, published in 1928, is considered to be a demonstration of Surrealism. *Nadja* recounts his relationship with an unpredictable and unconventional young woman, which was a pretense to an exploration of Breton's own self-identity. The unconventional and complex narrative of *Nadja* blends fact with memory and imagination, and with other writings by Breton. Roger Cardinal calls *Nadja* "a dossier on surreality, a treatise on chance and desire, a meditation on personal identity, an inquiry into paranormal experience, a narrative of a love-affair, an oblique manifesto about a certain way of living, an anti-novel, and an exercise in the stylistics of Enigma" (Cardinal 1987, p. 12). Both men and women produced provocative images of human sexuality and desire in painting, photography, and sculpture. René Magritte's *The Lovers* (1928) depicts a man and woman, with enshrouded heads, locked in an erotic embrace. Hans Bellmer (1902–1975) constructed a life-size doll, an articulated construction of wood, plaster, metal rods, nuts, and bolts, which represented a young girl and embodied the qualities of a surrealist object: subversive and erotic, sadistic and masochistic. In 1934, Bellmer published photographs of the doll with a prose poem as *Die Puppe* which drew the attention of the Surrealists who were exploring the multivalent possibilities of sculptural objects.

The surrealists invented a new form of sculpture, called assemblage, which offered new possibilities for creative interventions in life. Breton developed the theory of objective chance in which objects encountered in everyday life assume a kind of mystical presence, offering insight like a waking dream. In his essay "The Surrealist Situation of the Object," he wrote: "Thus I for my part believe today in the possibility and the great interest of the experiment that consists of incorporating objects, ordinary or not, within a poem. . ." (Breton 1972, p. 263). Always

mindful of the effect of a proposed new method, Breton noted that the object or visual element in a surrealist poem would give the reader a novel sensation, disturbing and complex. The goal of the object was “To aid the systematic derangement of all the senses... it is my opinion that we must not hesitate to *bewilder sensation...*” (Breton 1972, p. 263). Meret Oppenheim’s *Objet* (*Le Déjeuner en fourrure*), 1936, a fur-covered cup, saucer, and spoon, is the quintessential Surrealist object, evoking tactile sensations, which may attract or repulse, and connotations related to both fashion and luxury. Dalí attached the body of a lobster to a black telephone, thus producing an object both playful and disturbing. The crustacean’s sexual parts, located in the tail, are directly over the mouthpiece. Lobsters and telephones had strong sexual connotations for Dalí. Many surrealists, especially in the 1930s, began arranging objects in combinations which expressed unconscious desires and poetic associations. These “symbolically functioning objects” were exhibited at the Galerie Ratton in 1936 beside ritual objects from African and Oceanic cultures.

Bellmer’s photographs were equally important to Surrealism as the doll itself. He photographed the doll in black-and-white, then hand-tinted areas to heighten the ominous atmosphere in which the dismembered body appears to have been the victim of a crime. The art historian Hal Foster has written that “the dolls may go inside sadistic mastery to the point where the subject confronts its greatest fear: its own fragmentation and disintegration” (Mundy et al. 2001, p. 208). In “The Photographic Conditions of Surrealism,” Rosalind Krauss argues, photography was central to Surrealism, because it has the capability of recording the automatic writing of the world (Krauss 1981). “Surreality *is*, we could say, nature convulsed into a kind of writing” (Krauss, p. 29). Man Ray (1890–1976) made photographs, sometimes without a camera which he called “rayographs,” of household objects, some of which he labeled as “male” or “female”. With his assistant, the photographer Lee Miller, he produced solarized images of nudes and objects, which were ambiguous and uncanny. Maurice Tabard (1897–1984) used a variety of techniques

which involved chance or automatism, procedures such as double exposure, combination printing, and montage. The manipulated photograph introduced an element of the surreal and fantastic into a medium known for its indexicality, that is, a link with the real. Many different kinds of non-artistic photographs, from ordinary snapshots to police photographs, were published in Surrealist journals, with new captions (not original) in order to give the photographs new and unexpected meanings and thereby serve the surrealist agenda of disrupting social conventions.

Conclusion

The Surrealists took a stand against all forms of social and political control, from Fascism to Colonialism, using art and literature as a tool for liberation. One of their most successful strategies for social intervention was the Surrealist exhibition, staged in venues large and small with paintings, objects, non-art elements such as beds, braziers, and mannequins, miles of string, and bags of coal suspended from the ceiling, in order to create an immersive and interactive environment in which one could leave reality behind and discover aspects of one’s own self-identity (Jolles 2013). Surrealist exhibitions were deliberately disorienting, possibly provocative of anxiety as well as desire, both stimulating and revelatory of the power of art to change life and the power of the collective aesthetic experience (Mundy et al. 2001, p. 277).

After World War II, Breton returned to Europe, from his exile in the United States, and renewed surrealist activities in Paris. The movement drew new members into its sphere of influence from around the world. Artists employed some of the original automatic processes for generating new images. Surrealism’s ideas – the importance of the unconscious and the imagination, and techniques, like chance, automatism, and games like the exquisite corpse, influenced many of the postwar art movements and left an enduring impression on popular culture with the word itself “surreal” entering the lexicon to describe something which

is seemingly impossible if not improbable, or strange yet familiar. Surrealism, as discussed here, was characterized by the open-ended exploration of the relationship of the self and world which lay beyond immediate reality. Their investigation of new methods of creativity depended upon social interaction and the use of cultural resources to expand human possibility in thought and action.

College, Oslo, Norway

Abstract

The word “symbol” is derived from a Greek word meaning “to throw together.” It points to the fact that human beings have developed a way of transforming simple sensory material into a medium to represent something else. The medium becomes essentially human culture, which evolves over time. From this perspective, symbols can be broadly defined as *the capacity of expressing or representing one thing in terms of another*. For example, flag represents a nation; an animal the tribe or group; an antique clock the deceased relative who owed it; a swastika evil in the West and religion in the East; and a dream psychic conflicts or a future yet to come. While this general definition and the centrality of symbols for understanding human beings is generally agreed, there are nonetheless a variety of approaches available to the subject in the literature, each emphasizing different qualities in human life. This entry will review three key approaches.

Group processes · Play · Displacement ·
Symbolic remove · Protest

Introduction

Human beings should be defined as an “*animal symbolicum*,” a symbolic animal. Ernst Cassirer (1944) forcefully made this claim in his *Essay on Man*, arguing that philosophers’ earlier designation of “rational animal” was incomplete, as it confused a part for the whole. Few would, for example, label myths as rational, yet they have been more characteristic of human beings than philosophical systems or scientific analyses. Side by side with human conceptual reasoning we find poetic imagination, focused less on the expression of thoughts and ideas than on feelings and affects. The notion of symbol, in contrast to rationality, captures the rich variety of human life and its cultural manifestations. It is the key to unlocking the development of human civilization, as it takes form in language, myth, art, religion, and science. Cassirer himself analyzed how objects of human experience only emerge through these different “symbolic forms” and cannot be understood independently of them.

According to him, it is through the *mediation* of symbols that humans have irreversibly separated themselves from the *immediate* environment. There is no neutral or transparent medium for understanding the world, but rather each symbolic medium shapes reality to a particular form. As such, we are partly in dialogue with ourselves and our tradition when we explore objects of the world. Symbolic mediation has opened up a world of culture, a space of play and *possibility* for human beings. With symbols humans have progressively innovated new ways of interpreting and acting on the world and themselves. This entry will outline three classic approaches to symbols and how they open up different realms of the possible. They are symbols as: 1) motivated resemblances, 2) displaced desire, and 3) representations of a group. While not exclusive, these approaches capture a range of different research

areas, such as the development of children’s thought, personal meaning making, and collective bonding, respectively.

Symbols as Motivated Resemblances

The beginnings of representation require the support of a system of usable ‘signifiers’ at the disposal of the individual, and for this reason the child’s thought is much more symbolic than that of an adult (in the sense in which symbol is opposed to sign). (Piaget 1945/1962, p. 273)

In his *Course of General Linguistics*, Ferdinand de Saussure (1916) outlined a revolutionary approach to language as a system of signs. For him, a sign is composed of a *signifier* (sound image) and *signified* (concept), such as the word “tree” in English or “arbor” in Latin being used to stand for the concept of a tree. These parts are two sides of the same coin, differentiated from within and automatically associated in the brain of each speaker. However, signs take their meaning or value from their difference and relation to other signs within a system of language. Something is a tree because it is not a bush or a shrub. Saussure’s term “value” implies exchange value with other signs within a system, which is shared among speakers of a language community.

The defining feature of a sign for Saussure is its “arbitrary” character, meaning that signified and signifier are connected by a relationship of social convention rather than that of resemblance. The succession of sounds “t-r-e-e” has no intrinsic similarity to the concept of a tree, and as such there is nothing that would prevent it from having another *signifier* except force of social habit. There are, of course, exceptions to the arbitrariness of language that Saussure must deal with, such as explicative (e.g., ouch) and onomatopoeic (e.g., tick-tock, bow-wow) words. He points out that although these signifiers resemble or are contingent on the signified, they nonetheless vary between language and go through the same evolution as other signs in it. The noise a rooster makes in English, for example, is “cock-a-doodle-doo” and in Spanish “quiquiriqui.” Both share a

similar rhythm, mimicking a rooster, but differ significantly nonetheless.

In contradistinction to the arbitrary and conventional relation of *signs*, Saussure defined a *symbol* as having a “motivated” relationship and a “rudiment of a natural bond” (p. 68) between signifier and signified. Metaphors are a powerful example of this. The use of different body parts and actions to represent mental states, such as hunger through the stomach, is remarkably consistent across cultures (Shweder 1990). At the same time, because symbols are partially free of conventional constraints, they open up a possibility of playing with existing signifiers in a way that signs do not (as is particularly clear with living, creative metaphors). Thus, in a paradoxical way, we might say that the possibility of different signifiers for signifieds exists more *between* language communities for signs (given their arbitrary relationship) and *within* a language for symbols (as a creative and situated adaptation).

Piaget (1945/1962) picked up Saussure’s notion of symbol in his classic book *La Formation du Symbole chez l’Enfant* (The Formation of the Symbol in the Child), where he traced the origins and development of what he called the “symbolic function.” Its distinguishing feature is the ability to *represent* the world and thereby escape the present. As with his other work, development is explored in terms of the equilibration of the person and the environment through assimilation and accommodation of action schemes and cognitive structures. Early forms of the symbolic function involve imitation (where accommodation is primary) and play (where assimilation is primary). At this stage there is little differentiation between signifier and signified, from the standpoint of a child, and may even lead to a confusion of representation with reality (DeLoache 1991). Genuine differentiation happens with the different forms of representational activity that follow, such as imagination and symbolic play. Because children do not possess all the signifiers of socialized adults, their thought is in general more symbolic (in Saussure’s sense) than adults. Only gradually do the motivated connections between signifiers and signifieds become replaced by the conventional

ones that characterize socialized adult rationality – that is, signs replace symbols.

Children’s symbolic play is typically driven by fascination with objects, which are consciously re-evoked through another object, as when a broom is used to represent a horse or a rock a car (Vygotsky 1990). However, what is being represented can also be more unconscious and affective, relating to children’s desires and anxieties. For example, “a child who has been made jealous by the birth of a younger brother and happens to be playing with two dolls of unequal size, will make the smaller one go away on a journey, while the bigger one stays with its mother” (Piaget 1945/1962, p. 171). Piaget calls these “secondary” or “affective” symbols, which have been the main focus of psychoanalysis. Both forms of symbols are always present but to different degrees. In the next section we will consider in more detail how affective symbols operate in psychoanalytic thought.

Symbols as Displaced Desire

The formation of symbols also takes place normally. A soldier will sacrifice himself for a many-coloured scrap of stuff on a pole, because it has become a symbol of his fatherland, and no one thinks that neurotic. But a hysterical symbol behaves differently. The knight who fights for his lady’s glove knows, in the first place, that the glove owes its importance to the lady; and secondly, he is in no way prevented by his adoration of the glove from thinking of the lady and serving her in other respects. The hysteric, who weeps at A, is quite unaware that he is doing so on account of the association A–B, and B plays no part at all in his psychical life. The symbol has in this case has taken the place of the thing entirely. The pathological process is one of displacement, such as we have come to know in dreams. (Freud 1895, 349–350)

While Freud clearly recognizes the importance of symbols to human behavior in general, his primary interest was to explore how they operate in psychopathology. Rather than a conjunction between signified and signifier found in normal life, he focuses on cases where a psychic disjunction arises in order to protect the ego. In this case, the symbol is an expression of a repressed motive

or trauma to which the person is not consciously aware. The unconscious operates in terms of affects and through a *pars-pro-toto* (a part taken for the whole) logic. An original event may linger on in bodily memory of it, where it becomes symbolized through a particular body part. This may even involve a metaphorical link, as when a patient describes an insulting remark as a “slap in the face” and later develops a facial neuralgia.

In the language of psychoanalysis, the symbol is a “displacement” of an unconscious motive. This serves the psychic function of protecting the person from a painful memory or conflict. According to Freud, such symbol formations express an “over-determination of motive.” This is particularly clear in the case of dreams, where multiple motives may be expressed as a single dream image (Freud 1900), but psychoanalysis applies the principle to a wide range of different psychological phenomena, such as myths, humor, and slips of the tongue. The psychoanalysis is tasked with bringing this unconscious relationship to consciousness through techniques such as free association. In making the unconscious conscious the patient is able to work through the traumatic event.

Freud’s scheme in which an unconscious motive is displaced on the symbolic level is complicated by the notion of “symbolic remove” (Obeyesekere 1990), whereby one symbol can be substituted for another. In the association A-B in the quote above, B is replaced by symbol C and C by D, etc. As this substitution process precedes the link between the original motive and symbol becomes increasingly distant. Whereas Freud focused on *regressive* symbolization as a failure of sublimation, Obeyesekere highlights possibilities for *progressive* symbolization. He argues that for Freud the symbol remains largely on the level of a *symptom* (a displaced motive), where there is a direct relation between motive and symbol, while for him it can be transformed into a genuine *symbol* of spiritual and intellectual enlightenment.

In his classic book *Medusa’s Hair*, Obeyesekere (1981) interviews religious mystics in Sri Lanka that perform rituals, such as hanging

from hooks and walking on hot coals. Rather than considering these as pathological behaviors, he shows how the mystics work through psychic trauma with the help of collectively recognizable symbolic forms, which simultaneously reposition them within as spiritual leaders. Freud’s “dream work” becomes the “work of culture” (Obeyesekere 1990), whereby people appropriate and transform conventional culture for themselves, and the “overdetermination of motive” becomes an “overdetermination of meaning.” He weds psychoanalytic thought to anthropological investigation, in order to explore how culture operates at the levels of both the collective and individual psychic consciousness simultaneously. The analytic focus shifts to the process by which the individual transforms the collective cultural idiom through his or her “deep motivation” and in turn objectifies it as a new cultural object (such as reinventing a ritual). In this way, culture has built into its possibilities for transforming ourselves and the wider society.

Symbols as Representations of the Group

For Freud God is the Father; for Durkheim God is Society. (Evans-Pritchard quoted in Moscovici 1990, p. 37)

In his book *Elementary Forms of Religious Life*, Durkheim (1912/1965) analyzed symbols as being representations of a group, both expressing it and working to unify its members. He gives the example of an Australian tribe that sees itself as a totem animal, in a similar way that citizens will unify under a flag in contemporary nation-states. Durkheim theorized how symbols are creatively generated in collective rituals, where groups are innervated in reciprocal movement. In these moments of “collective effervescence” the group projects its feelings onto objects, transforming them into symbols that can act back on group members, continuing to socially shape their experiences. Such events, and the symbols that arise from them, function to reaffirm the bonds that hold the group together and in so doing give vitality to group members. By contrast the

individual existing alone grows weak and losses spirit.

These processes of inventing new symbols in collective gatherings can be observed in contemporary protests (Awad and Wagoner 2020). Protest movements develop symbols that hold people together and motivate them for a common cause. In this way they serve both to unify and mobilize people, reminding them of the values at stake and the gap between the current state of society and a possible future state. Consider the Arab uprisings which were first sparked in Tunisia, where a street vendor self-immolated when his cart was confiscated by police after failing to pay a bride. His case became a potent symbol of economic deprivation, corruption, and political neglect that resonated with general feelings among the population, and as such quickly became a rally point for nationwide protests. Although revolution was prepared for by an accumulation of grievances, it required that these be condensed into a concrete symbol of injustices against the Tunisian people for it to erupt. Once created, the symbol served as a motivating force and constant reminder of the revolutionary cause.

The protest example already extends the Durkheimian approach beyond a focus on group *consensus* and *stability* to one of *conflict* and *social change*, where symbols emerge precisely to further a group's project against other groups. This shift was powerfully developed by Moscovici's (2000) theory of social representations, which describes how new social objects (esp., scientific concepts) are transformed in the process of being understood and related to by the public. Such objects are signified in search of signifiers. In his original study, exploring how psychoanalysis entered the French public in the 1950s, Moscovici (1976/2008) shows how different groups represent psychoanalysis according to their own history and project for the future. The communist press, for example, sees psychoanalysis as a symbol of American capitalism, while the Catholic press sees its therapeutic benefits (being akin to their own practice of confession). It is important to emphasize that symbols here function not simply to define the current state of affairs but to help the group move toward a possible future that they are

already striving toward. In this way, they are key mechanisms linking the actual and the possible.

Summary

In this entry, we have reviewed three different approaches to how one thing is represented in terms of another through symbols, and the possibilities this opens up for human life. First, we explored how this very ability ("the symbolic function") grows out of the concrete activities of imitation and play in childhood. Possibilities of representation suddenly abound: Anything can potentially be used to represent anything else. The process is only constrained by the limitations of one's imagination. Second, we investigated how unconscious motives can be displaced onto objects, which in turn can be substituted with other symbols. This latter process of creating symbolic remove opens the possibility of progressively transforming what begins as more of a symptom of distress into a symbol of enlightenment. Finally, we touched on how groups project themselves onto objects to create symbols that build bonds between groups members and create an orientation to the future for them. Here symbols highlight the gap between the actual and possible state of society.

Synchronization

Ryszard Praszquier

University of Warsaw, Institute for Social Studies,
Emeritus, Warszawa, Poland

Definition

The phenomenon of synchronization (sync) appears within both inanimate matter and biological systems. The focus of this entry is the occurrence of human synchronization.

The concept of the free energy principle is presented as the core mechanism facilitating the formation of unison patterns. Some of them occur constructively, while others are dysfunctional. This is illustrated on the neuronal, interpersonal, group, and family levels.

Moreover, exemplary methods for “healing” dysfunctional sync are reviewed. In conclusion, it is suggested that further study of human sync could lead to techniques that contribute to higher levels of empathy and cooperation.

Keywords

Coordination · Brain-to-brain coupling · Rhythms · Social sync · Family therapy · Gestalt therapy · Conflict transformation

Introduction

Systems as diverse as clocks, metronomes, singing crickets, cardiac pacemaker cells, firing neurons, menstrual cycles, coupled lasers, fireflies, and applauding audiences exhibit a tendency to operate in synchrony (Pikovsky et al. 2003; Strogatz 2003). This phenomenon is universal and relates to inanimate matter, as well as to biological systems, including brains, individuals, groups, and families. These synchronizations are fascinating, both for scientists, analyzing sync mechanisms (e.g., Albert Einstein, Henri Poincaré, Niels Bohr, Norbert Wiener, and others; see: Strogatz 2003), and lay observers, seeing how elegantly metronomes synchronize,¹ birds form a V-shaped flock,² and audiences clap in rhythm.³

It is likely that the phenomenon that triggered scientists' interest in analyzing synchronal rhythms were fireflies. One of the first articles on these unison-blinking insects appeared in 1917 in the journal *Science* (Laurent 1917). More recently, in the 1990s, public interest was aroused by stories of blinking-in-unison fireflies in the Great Smokey Mountains, USA. In Thailand, a scientist conducted a small experiment that involved capturing several fireflies and releasing them in a dark room. Soon, pairs and trios began to pulse in unison. The synchronized groups grew until all of the fireflies were blinking on and off as one (Strogatz 2003, pp. 12–13).

Strogatz compared fireflies to so-called “oscillators,” and, for decades, the aforementioned mathematicians and physicists tried to understand the mathematics of their coordination.

The focus of this entry is on human sync, i.e., how minds, individuals, and groups synchronize, and the results of this process. Synchronization among humans seems an avenue to “the possible,” as it facilitates the synchronized actions (Fitzpatrick et al. 2016), better communication

and social coherence (De Vignemont and Singer 2006), increased task performance (Barsade 2002), and better cooperation (Wiltermuth and Heath 2009).

Synchronization may lead to positive or negative results, and may appear on various levels, e.g., the neural, family, and social levels. In negative cases, there are some helpful concepts for “healing” maladaptive sync patterns, e.g., specific therapeutic processes and conflict transformation projects.

Synchronization: A Prevailing Phenomenon

Synchronization is the coordination of events to operate a system in unison; it is a

pervasive concept relevant to diverse domains in physics, biology, and the social sciences (Ramseyer and Tschacher 2006). Sync can be considered if the properties of two subsystems (parts of a larger interacting system) agree in time (Brown and Kocarev 2000).

Free Energy Principle

The free energy principle describes how systems (e.g., biological or neurological) maintain stabilization through self-limitation of the number of states (Ashby 1962). Systems minimize the amount of states and the level of energy through modifying their own configuration (Friston et al. 2006).

Sync is a natural state in which self-organizing systems strive for a state of minimum energy, according to the free energy principle (Ashby 1962; Friston et al. 2006; Friston 2010). An emergent property of this process is synchronization.

A good illustration of this is at the brain level, as the brain minimizes free energy, striving for a stable state (Koban et al. 2019). It is synchronization that enables the functioning of the free energy principle, as sync is the lowest-energy state (Leclère et al. 2014). Some authors have posited that synchrony is an emergent property of free energy minimization; therefore, synchronization is a state of a “resting brain” (Palacios et al. 2019).

Constructive Sync

Neurons and Their Functional Units

New challenges trigger the appearance of new neuronal functional units in the brain, i.e., coherent neuronal structures that function to accomplish tasks (Nowak et al. 2020). The sync provided by the formation of functional units may be transient, persisting only as long as necessary to perform the task at hand (Nowak et al. 2017).

These new neuronal functional units are often organized around solving new problems, generating creative solutions, or around empathetic “feeling into” newly encountered others (Praszkier 2014); as such, they play a constructive role.

Brain-to-Brain Coupling

When individuals synchronize, it has an impact on their brains, as they correlate with the emergence of an interbrain synchronizing network (Dumas et al. 2010).⁴ For example, a study documented that synchrony of both fingertip movement and neural activity between two participants increased after cooperative interaction (Yun et al. 2012).

Brain-to-brain coupling looks like a wireless communication system in which two brains are coupled via the transmission of a physical signal (e.g., sound propagation) through the shared physical environment (Hasson et al. 2012). This was confirmed by various scanning methods. MRI testing documented that during successful communication, the speaker’s and listener’s brains exhibit joint, temporally coupled response patterns that synchronized over time (Hasson et al. 2012). Moreover, EEG scans of pairs of subjects imitating one another revealed that states of interactional synchrony correlate with the emergence of an interbrain synchronizing network (Dumas et al. 2010).

These findings were confirmed using fMRI to record brain activity of both speakers and

⁴In the brain regions that play a pivotal role in social interaction, i.e., alpha-mu band between the right centroparietal area.

listeners during natural verbal communication. During successful communication, speakers' and listeners' brains exhibit joint, temporally coupled response patterns. Additionally, more extensive speaker–listener neural couplings result in more successful communication (Stephens et al. 2010).

Child Development

Synchronization supports many human activities. It is instrumental for a child's successful development: Sync is seen as a formative experience for the maturation of the social brain, impacting the development of self-regulation, symbol use, and empathy across childhood and adolescence (Feldman 2007).

The ability to achieve synchrony may represent a crucial developmental achievement for significant dyadic relationships—ones that facilitates social, emotional, and cognitive growth for the child (Harrist and Waugh 2002). Moreover, family harmony and adult–child synchrony are critical for an adolescent's successful social adaptation (Barber et al. 2001).

Groups

In groups, synchronization increases the tendency to cooperate and to maintain positive relationships (Tschacher et al. 2014; Wiltermuth and Heath 2009). It also decreases the occurrence of conflicts and increases the efficiency of task groups (Barsade 2002).

Group members tend to like and have more compassion for those with whom they are synchronized (Hove and Risen 2009; Valdesolo and DeSteno 2011), and are more eager to cooperate with them (Lang et al. 2017; Wiltermuth and Heath 2009). Generally, people tend to be more prosocial after synchronizing behaviors with others (Hu et al. 2017).

Destructive Sync

In the Brain

The synchronization of neuronal activity in the brain may be a determinant of several mental disorders, such as obsessive–compulsive disorder

or epilepsy (Özçoban et al. 2014; Tass et al. 2003). New theories of the formation of epileptic networks in the brain indicate synchronization of particular regions of these networks (Geier and Lehnertz 2017).

Interpersonal Relationships

In the psychology of intergroup aggression, there is a known phenomenon of synchronizing the mimicry and gesticulation activities of the participants of aggressive mobs (Goldstein 2002; Hatfield et al. 1994).

Family Dynamics

On the family level, there are known sequences of repetitive behavioral patterns, which contribute to destructive outcomes (Nowak et al. 2020). In some cases, the tension sensed in the behavior of one spouse may trigger aggressive behavior in the other spouse and odd reactions from one child, while another child may tend to withdraw; after a final outburst of emotions, the family dynamics calm down, and recurrently reappear after a period of time.

Similarly, regular reoccurring patterns may be perceived as destructive, on the one hand, and as paradoxically uniting the family around the appearing symptoms, on the other hand (Fiese et al. 1993; Minuchin 1974; Palazzoli et al. 1977, 1978; Wolin and Bennett 1984).

Dysfunctional into Functional Sync

Psychotherapy

Psychotherapy is a collaborative treatment based on the relationship between an individual and a psychologist, grounded in dialogue that allows the individual to talk openly with someone who is objective, neutral, and nonjudgmental. The aim is to work together to identify and change the thought and behavior patterns (i.e., sync sequences) that keep the patient from feeling good (Hamlyn 2007; Wampold 2019).

Sync and Therapeutic Relationships

The studies related to synchronization in psychotherapy are mostly focused on the positive impact

of synchronization of the psychotherapist–patient relationship and the way it influences the outcomes of psychotherapy (Koole and Tschacher 2016; Ramseyer and Tschacher 2008, 2011; Tschacher et al. 1998).

Sync between the therapist and the patient manifests both on the interpersonal level, as well as on the speech and movement feature level (Schiepek 2009), i.e., the way verbal and nonverbal fixed sequences arise (Tschacher et al. 1998).

Kinesthetic coordination (Dittmann 1987) is usually detected by motion energy analysis (MEA),⁵ revealing, for example (on the $N^o = 70$ patients sample), that head movements correlate with the overall results of the therapeutic process, while the sync of body movements correlates with the result of a particular session (Ramseyer and Tschacher 2014). This is probably because body movements are more automatic and do not involve conscious analysis, whereas head movements may reflect considerations related to the entire process (Dittmann 1987).

Generally, the level of synchrony of the interactions of interlocutors may contribute to the outcomes of their conversation (noted by neurolinguistic programming [NLP], a therapeutic method) (Dilts et al. 1980).

Family Systems Therapy

Over time, families develop habits and rituals involving both patterns of behavior and emotional reactions. When occurring regularly, these rituals become synchronized, many of them being positive (according to Carl Jung's theory of the reassuring role of rituals), bringing stability and messages of love and care.

However, in some cases, sync stabilizes over dysfunctional issues, e.g., around avoiding some threatening problems. This process may lead to increasing problems and impairments.

The family systems therapy approach perceives family rituals as essential (Fiese et al. 1993; Palazzoli et al. 1977, 1978; Wolin and Bennett 1984). Along these lines, the concept of family

systems therapy (FST) was developed, based on the general system theory of the 1960s (Bertalanffy 2015)⁶ and Murray Bowen's systemic insights (1976; 1978), perceiving the family as a whole, autonomous system (Keeney 1983; Nichols 1984). Specific techniques were developed to remove dysfunctional sync, eventually replacing it with a functional one, without shattering the fragile family balance (Nowak et al. 2020).

Gestalt Therapy

Kurt Lewin's conception of the field theory (Lewin 2004), grounded in Gestalt psychology (Burnes and Cooke 2012), was based on the premise of seeing the situation as a whole (Lewin 2004); in other words, perceiving dynamic systems instead of single elements.

This is a synchronous process: Usually, new “wholes” (gestalts) emerge after playing their roles, are removed, so that space is created for new gestalts. However, in some cases, the existing gestalt is not fulfilled or gratified, and as such—while other needs are more pressing—it is moved into the background. If unsatisfied, it lingers and “retroreflects” (i.e., turns back) in the background, popping up through some unintended movements (e.g., tapping a finger) or actions (e.g., emotions transferred to someone else). This kind of a dysfunctional gestalt shatters synchrony, often unknowingly.

Gestalt therapy (grounded in the concept of *phenomenological experience*) (Crocker 1999; Latner 2000; Melnick and Nevis 2005; Yontef 1993) was created by Frederick Salomon Perls (1992a, b). Its core idea was based on shifting the awareness from interpretations and attributions to experiencing the “here and now,” and in this way, deconstructing old dysfunctional gestalts and recomposing them on a new functional level. By doing so, a new adaptive synchrony is created and constructive sync is maintained.

⁵See, for example: <https://www.youtube.com/watch?v=sHBxBC01pd8>; accessed 03.05.2021.

⁶Developed in the 1950s and 1960s, mostly in Palo Alto, by Gregory Bateson, Jay Haley, Donald D. Jackson, and Paul Watzlawick; later, in the 1970s, also by Salvador Minuchin, Virginia Satir, and the Milan School (Mara Selvini Palazzoli).

Social Change: Conflict Transformation

Intractable conflicts lead to developing a specific sociopsychological infrastructure, which includes collective memory, an ethos of conflict, collective emotional orientations, and societal beliefs (Bar-Tal 2009). Periods of conflict often alternate with truce, forming a specific rhythm.

People get used to conflict environments and feel insecure when peace comes about (Praszkier et al. 2010). In this vein, it seems essential to transform the sociopsychological context so that it becomes a peace-enforcing environment (Lederach 2003; Miall 2004).⁷

For example, Dr. Yehudah Paz, from Israel, is currently building islands of peace in the Middle East region.⁸ He is convinced that mere conflict resolution is not enough, given that peace leaves a void, which is very often difficult for people used to war to bear, especially if they see no other prospects. Based on this philosophy, he involves women from clashing groups in profitable joint ventures. Through cooperating in these ventures, Israeli and Arab women experience benefits engendered by joining forces and generating profit.

Along these lines, peace becomes a wanted state, as it provides profit and new prospects; it also alters the old conflict narratives, replacing them with stories of success and profit through cooperation and trust (Praszkier et al. 2010).

This illustrates the process of conflict transformation, replacing the “old” conflict-based sync with synchronization around positive factors.

Summary and Conclusions

There is a tendency in nature to synchronize, relating both to inanimate matter and to biological systems. In many cases, this is an adaptive and constructive process, helping birds to form efficient V-shaped flocks or individuals to increase

their level of empathy. One explanation of this synchrony is the free energy principle, enabling systems to achieve the most efficient energy balance.

The effect of the synchronization of systems or subsystems may be positive, e.g., the appearance of neurons forming functional units, better understanding between individuals, or better cooperation in groups. There are also situations when synchronization is maladaptive, e.g., epileptic brain circuits, intergroup aggression, or family dysfunctional patterns.

Fortunately, there are several paths for “healing” dysfunctional sync, e.g., psychotherapy or social entrepreneurship aimed at conflict transformation.

From what has been discussed so far, it seems justified to conject that synchronization augments “the possible” (see: Glăveanu 2018). One of the most interesting examples of this positive influence is synchronization through dancing. The studies thus far indicate that dancing augments empathy (Bergland 2013; Hagendoorn 2004; Powers 2010). Dance involves tuning into another’s movements, intentions, and emotions (Christensen et al. 2016). Couples that dance, especially aging couples, are healthier and live longer; moreover, dancing reduces the risk of dementia (Powers 2010) and helps alleviate the symptoms of Parkinson’s disease (Park et al. 2020). Therefore, it may be advantageous to continue exploring how common rhythm and synchronous behaviors contribute to people’s well-being.

Finally, the influence of synchrony on a group’s effectiveness may be worth further research. As mentioned before, it has been documented that synchrony with others can increase cooperation by strengthening social attachment among group members (Wiltermuth and Heath 2009). It may be worth exploring how common sync-building rituals, e.g., group dancing,⁹ build better understanding and cooperation.

⁷This is the reason why this approach would support the notion of “conflict transformation” rather than the more technical and narrowly defined “conflict resolution” (Lederach 1996).

Talent Development

Jonathan A. Plucker¹ and Kristen G. Fickes²

¹Center for Talented Youth and School of Education, Johns Hopkins University, Baltimore, MD, USA

²Emory H. Markle Middle School, South Western School District, Hanover, PA, USA

Abstract

Talent development is an approach to education for advanced achievement. Traditionally, many models of advanced education focus on the identification of young people who are already performing at high levels, interpreting that performance as evidence that the student needs additional advanced services. In contrast, talent development focuses on providing opportunity to young people who may have the potential to perform at those advanced levels. This talent development approach, with its focus on potential rather than performance, tends to incorporate inclusive, developmental, and sociocultural perspectives that emphasize striving toward the possible over living with current realities.

Keywords

Talent development · Domain specific · Development · Psychosocial factors

A longstanding problem with advanced education programs is that they appear to serve some groups of students well while ignoring other groups entirely. Consider the case of a school district in the mid-Atlantic region of the USA. The district enrolls nearly 5500 students, but all of the students identified as gifted and talented come from two of the district's seven schools. This is not uncommon, with most school districts (New York City Schools being the most obvious example) experiencing similar patterns. This patchwork of academic talent has less to do with the capabilities in any one school and more to do with the fact that American students still primarily attend their neighborhood schools. With well-entrenched residential segregation in housing, demographics are often highly dissimilar across a school district's buildings (Plucker and Peters 2018). The movement away from traditional gifted education models toward talent development (TD) models is specifically aimed at providing young people the opportunity to explore what is possible of themselves, as what is possible of their futures.

An exploration of Subotnik et al.'s (2017a) model, as well as discussion of key conclusions and future recommendations for this approach to talent development, will allow the reader to understand why this framework is beginning to emerge as a model for what is possible in gifted programming. In November of 2015, the National

Association for Gifted Children (NAGC) finalized a three-part report on talent development. The NAGC board of directors believed further research on talent development was warranted as giftedness is now thought to be “multi-faceted, domain-specific, developmental, observable through achievement, influenced by a variety of psychosocial factors, and vulnerable to loss if neglected” (National Association for Gifted Children 2015, p. 5). A sociocultural approach, the talent development framework steps away from the entity views of intelligence (i.e., focusing interventions on students who are already performing at high levels), instead aiming to transform one’s potential into high achievement (see also Plucker and Barab 2005; Plucker et al. 2017). Rather than focusing on what already is recognized and realized about student talent, the talent development framework reshapes gifted education by shifting toward what is possible. Additionally, this reshaping could redirect the focus of teacher training and gifted programming. Instead of emphasizing identification, teacher training and gifted programming could center on an approach to cultivate the talents of potentially high-achieving students. Moreover, legislative and corporate support for gifted programming could increase as the talent development approach aims to “prepare talented individuals for outstanding creative productivity or high levels of contribution to a domain and to our world” (National Association for Gifted Children 2015, p. 6).

A talent development framework for gifted education revolves around basic principles that support the modern view of giftedness. To begin, in a talent development framework, domain-specific abilities and general intellectual abilities are equally valued. These abilities “are malleable and need to be cultivated” (National Association for Gifted Children 2015, p. 5). Fostering a child’s academic and social-emotional development requires parental guidance and knowledge of educational opportunities. Beginning with potential, a talent development framework views giftedness in different stages. From potential, “Giftedness transforms from competence to expertise to distinction in achievement or creative productivity”

(National Association for Gifted Children 2015, p. 5). In its early stages, a talent development framework identifies individuals with potential, whereas in its later stages, the framework emphasizes the achievement and productivity of individuals. Emphasizing potential when identifying students for gifted programming grants previously underrepresented populations access to services. Furthermore, the trajectories of different domains are not parallel. Each domain has different beginnings, peaks, and endpoints. In most domains, potential is observable during early childhood. However, certain domains require the acquisition of basic skills or physical maturation before talent is noticeable. Therefore, both parents and educators should continue to identify individuals whose potential may become apparent at a later point in time, reinforcing that an individual’s possible selves may develop throughout one’s lifetime and are not set in stone at an early age (Zittoun & de Saint-Laurent 2015).

Since giftedness is malleable, a comparison group of individuals with similar educational experience or background characteristics should be used for eligibility of services within a domain. Students who are eligible for gifted services yet are not achieving in the classroom should receive school counseling and psychological services to counteract any factors thwarting achievement. A comprehensive evaluation may be necessary to understand possible causes of and solutions for the underperformance.

Throughout the stages of talent development, children should be exposed to a variety of programs, teachers, and instruction. The rate at which an individual progresses through the stages of talent development will vary. For example, students who are economically disadvantaged may have less exposure than other individuals, causing a delay in their development. Conversely, talent development can be accelerated in individuals by the exposure to enrichment opportunities, as well as the assistance of an effective support system.

Striving for greatness, gifted children must be persistent, practice strategic risk-taking, and have self-confidence in order to develop their talent (Subotnik et al. 2017a, p. 254). Although these

characteristics may not occur naturally in certain individuals, coaching and instruction can ameliorate these psychosocial variables. The opportunities to cultivate one's abilities must go beyond the home and school. To fully develop one's potential, an individual must explore and engage with opportunities at local, regional, and national levels. These experiences should include authentic interactions with professionals within a particular field. By interacting with role models and mentors, children receive exposure to new ideas and concepts, allowing them to see what is possible for themselves.

To foster the abilities of talented individuals, gifted programming should include short-term and long-term goal setting for students. Each pathway in a gifted program should allow for participants to access high-level opportunities within a particular domain. For participants with families who lack knowledge about these opportunities in certain fields, gifted programs should provide students the means to access these opportunities.

Subotnik et al.'s Megamodel

The most significant conceptual advance in talent development occurred with the creation of Subotnik et al.'s (2011, 2017a) megamodel for talent development. The model's systematic approach focuses on domain-specific ability rather than global ability, contending that the sole factor for adulthood eminence is not a high general cognitive ability as measured by IQ or similar tests. This emphasis on high general cognitive ability, which is prevalent in gifted education models, systematically limits the possible by excluding various types of talent and types of potential recognized in young people. Rather, Subotnik et al. (2017a) point out accomplishments in adulthood are actually linked to domain-specific abilities, noting their importance in certain athletic, performing arts, and other professional fields. For example, spatial reasoning is important to success in several STEM and artistic fields, and technical skills distinguish elite from less proficient athletes (Elferink-Gemser et al. 2007; Lubinski, 2016; Stieff, 2013). Beyond

domain-specific ability, Subotnik et al. (2017a) believe deliberate practice and study are the other factors necessary for talent development.

To apply the model, one needs to first understand the two types of individuals who pursue creative fields and careers. The performer "uses his or her body, voice or expression to interpret a piece of music, written word, or physical challenge," and the producer "choreographs, composes, invents, or researches a problem" (Subotnik et al. 2017a, p. 256). To succeed within a domain, both performers and producers must obtain the necessary skills and content knowledge. Through deliberate practice and study, these individuals then foster their abilities. With the necessary commitment and motivation, certain individuals can propel further ahead; whereas, a lack of these characteristics – and, perhaps more to the point, a lack of opportunities to develop commitment and motivation – can limit success. With the assistance of mentors, both performers and producers are able to gain an understanding of the domain's values.

Notable differences exist between the two groups. For example, through the practice of specific skills, a performer is more readily able to view their results. Meeting explicit benchmarks allows a performer to note their progress and growth. Furthermore, a performer might only be able to operate at peak performance for a limited period of time. Additionally, the input of experts within a field is greatly valued by this group. Performers are also explicitly instructed on psychosocial skills throughout their training. Lastly, culturally, performance domains are of greater value than production domains, specifically those of which are academic. Therefore, during adolescence, certain aspects of the performance domain can offer insight into the talent development of academic domains (Subotnik et al. 2017a).

The conceptual benefit of the producer category is considerable, given that it broadens our perspective on who can be considered talented in the present and who may be considered talented in the future. In this way, the idea of talent development of producers directly links to Glăveanu's (2018) description of possible selves. The more

opportunities we have to view a broadened range of children as being potentially talented, the greater the chance that they will understand the range of possible selves – and likely possible futures – available to them.

Identification in Music

Consider, for instance, how potential is transformed to achievement within the field of music. To begin, the identification of high potential occurs at a young age in a manner that is “content valid” (Subotnik et al. 2017a, p. 258). While the child is performing (i.e., singing or playing an instrument), both pitch and general musicality are observed. As the students crossover into the achievement stage, the pieces they are asked to perform during auditions are made public. Knowledge of this information is advantageous to the individuals who are able to access it. Despite having high potential, certain individuals without access to this knowledge or other resources, such as instruments or teachers, are at a distinct disadvantage.

Furthermore, benchmarks for success in music are held each year by a performance that takes place in front of the members of their musical area (i.e., chorus). Continuing on within the program means one must succeed within this venue. Additionally, students are given individualized lessons that focus on their own strengths and areas for improvement. Instructors also work to curb any anxieties their students might face when performing. Whether a student wants to become a music teacher or a concertmaster, a well-developed music program will develop a personalized pathway for its students (Subotnik et al. 2017a). The personalized pathway then allows for the student to explore possible selves within the domain of music. Having access to opportunities like this is paramount when cultivating the talent of individuals – regardless of the field.

Identification in Mathematics

Mathematics is an academic domain where an individual is able to demonstrate high potential

at a young age, with over 15% of American students performing at least three grade levels ahead of their chronological age through middle school (Peters et al. 2017). A child who attempts to “mathematize” the world at a young age will identify patterns and count various objects. For instance, when given a few skittles from a parent, a child with the capacity for exceptional mathematical reasoning may group the candy by color. The child might even attempt to ensure that each color group contains the same exact number of skittles. If the child has a sibling, it might count and compare the number of skittles he/she has to the number of skittles his/her brother has. One parent observed her son “mathematizing” the world during lunchtime; she noticed him grouping his fish sticks into math problems as he ate them.

With parental support, these children begin their formal education with advanced mathematical computational and reasoning skills. Oftentimes, these individuals are then those selected for early acceleration in mathematics. Children from socioeconomically disadvantaged homes may not have access to the same early opportunities as their peers. Therefore, schools must ensure that their pre-schools and elementary schools supply students with enrichment opportunities that explore mathematical concepts. These opportunities allow educators to look for those children who not only “mathematize” the world but also express exceptional interest and demonstrate rapid skill acquisition in mathematics.

To measure one’s academic development in mathematics, achievement tests are used. The results of these assessments determine the necessary services to be provided to the student. An example of these services includes subject area acceleration. The pacing of instruction can also be increased to match the rate of students’ acquisition of skills. In elementary school, to ensure that those who might develop later in the field are identified, and after-school and in-school enrichment should be offered. For example, an intermediate school in South Central Pennsylvania offers a 43-minute enrichment period to its students. One of the options available to students is Barbie Bungee, a math enrichment where students have to design a bungee cord for Barbie, using math to

conduct an experiment, as well as to make and to test predictions. Opportunities for enrichment such as this give students the exposure to mathematics that is necessary to pique one's interest and motivation.

When a student gets to middle school, above-grade-level testing should be used as the testing has "immediate utility" and "predictive validity" (Subotnik et al. 2017a, p. 259). Tests such as the Preliminary Scholastic Assessment Test (PSAT), the American College Test (ACT), or the Scholastic Assessment Test (SAT) have high ceilings, allowing for better estimates of a talented student's mathematical reasoning ability, which in turn provide better information about the most appropriate option for placement. While completing Algebra I in eighth grade may serve as sufficient acceleration for one student, another student may require further acceleration.

Beyond in-school and after-school enrichment, schools offering a talent development program could ensure that students have access to math competitions, as well as after-school math clubs. For instance, competitions such as MATHCOUNTS, Math Olympiads, and 24 Challenge afford middle school and high school students the chance to compete against their peers in a variety of events.

To further develop talent, mathematically talented students should be advised by school counselors and mentored by professional mathematicians. Although schools may not offer all of the necessary advanced math classes a student needs, school counselors should be able to identify online or dual enrollment courses that would develop the student's mathematical talent. Ensuring that students from low-income families have access to opportunities outside of school is the work of the school counselors, as well as the organizations themselves – that guidance is pivotal to open up new possibilities for students furthest from opportunity. Another task of school counselors is to locate adult professionals to mentor their mathematically talented individuals. Allowing students the chance to network and to engage with these adult professionals helps the student to understand the demands of the field. For students who do not receive guidance from their own families, this

interaction and resulting advice is a salient aspect of the mentorship. In addition to guidance, mentors can also supply students with information about internships and trainings (Subotnik et al. 2017a).

Identification in English Language Arts

In English Language Arts (ELA), talent is manifested early in "word play, verbal analogies, word games, or early reading" (Subotnik et al. 2017a, p. 261). While on a road trip, young children who demonstrate high potential in ELA might point out letters and words that rhyme. One student, a third grader, as well as a fan of analogies and alliteration, once told his mother about his sister, "Isabella is cuter than a coyote's cousin!" As with math talent, knowing how to observe for these patterns in behavior and thinking of young people can help adults expand their ideas about what is possible for each child they nurture and support.

As the talent continues to develop, individuals "may proceed to a passion for writing short stories, plays, or poetry, or creating books, newspapers, or magazines" (Subotnik et al. 2017a, p. 262). The same third grader mentioned above is well known for his improvised poems. On one occasion, when his mother's friend was not feeling well, he asked his mother to record him performing this poem for her friend.

"Sometimes you think the stomach bug will never come again,

But then it comes back.

You should lock it in a pen.

So here's how to get rid of the stomach bug.

Make sure you only take the doctor's specifically prescribed drug.

(In a whisper) Or medicine.

Secondly, get lots of rest.

Third, eat healthy food.

Fourth, please get our video, it will put you in a good mood.

So next time the stomach bug strikes, you know what to do.

And remember, lots more sicknesses can happen just to you!"

When identifying potential and providing instruction in ELA, it is important for educators to

broaden their construct of literacy to include other culturally rooted forms, such as storytelling from indigenous roots and hip hop from African American roots. This expanded view increases equity and extends young people's concept of valuable forms of written and verbal expression to include their communities and identities. The recognition and celebration of these other forms of literary prowess will show students what is possible for themselves and their futures.

In elementary school and middle school, the instruction of ELA programs should be to cultivate a strong foundation in written expression. A program like Kid Writing take a systematic approach to writing workshop for elementary school students. To further enhance writing talent, students will need to engage in writing in a variety of modes. Though schools often value modes of writing like informative and persuasive, it is vital that students confer and receive feedback on their creative writing as well. Employing a reading and writing workshop model, such as that suggested by Atwell's (2014) *In the Middle* or Gallagher and Kittle's (2018) *180 Days: Two Teachers and the Quest to Engage and Empower Adolescents*, cultivates talent through its personalized and student-centered approach.

In middle school and high school, courses should focus on literary analysis. Students should be exposed to a variety of mentor texts, studying the craft moves of the authors and replicating their techniques. Integrating the techniques of experts into their writing, students evolve their own craft, so they can then participate in competitions. These competitions provide students a benchmark for their development, an opportunity for feedback from professional writers, and a chance to connect with other aspiring writers. Moreover, enrichment opportunities in ELA should be available to students. Examples of these extracurricular activities include speech or debate club, drama club, and creative writer's club. Working to develop the school's newspaper or literary magazine is another way to expand what is possible with one's talent.

Just like students are advised in other domains, counselors and educators should help

talented writers identify organizations where a student's work can be published. It is vital that educators be connected to professional networks within their field, so students have the opportunity to connect with mentors or professional writers. For example, the National Council of Teachers of English publishes information about summer institutes, online events, and networking opportunities, where educators can learn how to better support their talented students. As a student's talent advances, if rigorous courses are not available within the school, counselors should propose alternative options to students, such as dual enrollment or distance learning (Subotnik et al. 2017a).

Key Conclusions and Recommendations for the Future

Concerns

The talent development approach to advanced education and child development is relatively new, and as such, its potential value needs to be weighed against significant concerns that have emerged. For example, there is a sense that the talent development framework deemphasizes domain-general talent, at least as traditionally represented by psychometric constructs, such as general intelligence (Plucker and Shelton 2015). Therefore, does a focus on domain specificity of talent versus domain generality mean that every child is talented in something?

If so, this raises questions about feasibility with such a large-scale approach to talent development. But those concerns should be counterbalanced by the advantages provided by broader conceptions of relevant domains and cultural perspectives that likely lead to children and adolescents being able to view themselves across a wider range of possible selves, possible worlds, and possible futures (Glăveanu 2018). From this perspective, perhaps the increasingly common, equity-focused question within the field of education "Who gets to be talented?" should be asked differently: Who gets the opportunities to view and develop their possible selves?

Another concern is that, given the sociocultural approach to talent, high levels of skill do not reside within the individual but rather in the interaction between the student, peers, and the social context; the practical implications of this perspective are that talking about “profoundly gifted students” does not make much sense as talent is something that emerges from interactions and does not exist within someone. This lens on talent makes it highly appropriate when the concern is about closing excellence gaps that have formed as the result of students not receiving high quality, rigorous education and support, but it may be a threatening approach to advocates, educators, and parents of students who are already performing at high levels and receive special services as a result of being labeled “a gifted child.”

In a related vein, the emergent, sociocultural nature of talent within TD frameworks further challenges the “special child” approach to advanced education due to its allowance for talent to emerge at various times – implying that talent may surface at unexpected or unanticipated times. A contextual approach to advanced learning is hardly new (see the classic models of Renzulli and Reis 2018), but it is a foundational concept in most TD models and expands what we imagine is possible for talent development for people across the lifespan.

Additionally, the focus on eminence in the Subotnik et al. model has been questioned. The authors have responded to these concerns on multiple occasions (e.g., Worrell et al. 2012; Worrell et al. 2018) by noting that eminence, defined broadly, is part of several gifted and advanced education models, and that their emphasis on eminence as the ultimate goal of TD programs has been mischaracterized.

Finally, TD models have not been subjected to rigorous research on their implementation and efficacy. This lack of empirical support is not surprising given that this approach to advanced education remains relatively new, but a number of articles have appeared recently proposing innovative strategies for implementing TD models (e.g., Subotnik et al. 2017a, b, c), and Project EXCITE, a Chicago-based program using talent

development principles, has been carefully evaluated and studied (Lee et al. 2009; Olszewski-Kubilius et al. 2017). However, these efforts have largely been conducted by the originators and popularizers of the TD approach, and having third-party evaluations would provide an additional degree of confidence in this research (see Preckel et al. 2020).

Promise for the Future

Regardless of these concerns, the talent development approach to advanced education holds significant potential for impacting children’s possible lives in positive ways. First, the available models emphasize the distinction between high performance and high potential, noting that a lack of high performance does not necessarily lead to a lack of potential. Second, the approach may lead to effective strategies for helping low-income and racial/ethnic minority students develop their talent potential into important achievements. Third, the emphasis on domain-specific talent development, in which a student’s aptitudes, interest, and motivation within a single domain are valued of and by themselves, without regard to the student’s attributes in other domains, changes the emphasis from a search for all-around high performers to identification of advanced achievement in specific areas, further broadening what is possible in how to identify who is and can be considered talented. Work remains to be done before the talent development mindset can be considered an effective, viable model for advanced education, but initial conceptual intervention and empirical work provide a promising path through which young people can view their possible selves and the possible futures to which they can create and contribute.

Theory of Mind

Laura Franchin

Department of Psychology and Cognitive Sciences, University of Trento, Trento, Italy

Abstract

The theory of mind (ToM) refers to how people understand their own thoughts and feelings and those of other beings. It is a crucial cognitive mechanism for social interactions and communication. It helps us to predict, to explain, and to manipulate behaviors or mental states. Moreover, this skill is shared by almost all human beings beyond early childhood.

The literature presents different explicit false-belief tasks as a means of investigating ToM in children (e.g., one of the most famous is known as the Sally-Anne task). Although children younger than 4 years usually fail in these explicit tasks, it cannot be excluded that some less complex forms of understanding mental states develop earlier. So, in order to investigate the precursors that anticipate the emergence of a more mature representational system, many recent studies on infants' beliefs have demonstrated, in the last decade, a very early sensitivity specifically to the false beliefs of others by using implicit looking-time tasks. This entry starts with the definition of the theory of mind and its history, before moving on to summarize developmental research in this area. Finally, it focuses on the relation between theory of mind and the *possible* with some reflections on how an increasing consciousness of the variety of situations that the possible presents to us could allow people to choose the best alternative for themselves and others.

Keywords

Theory of mind · ToM · Mind reading · Mentalizing · Folk psychology · Possible

Definition and History

The theory of mind (also known by the acronym ToM) refers to how people understand their thoughts and feelings and those of other beings. This ability is also known as “mind reading,” “mentalizing,” or “folk psychology.” It is one of the most important cognitive mechanisms underpinning social interaction and communication. It helps people to predict, to explain, and to manipulate behavior or mental states. ToM implies deriving what the others think from signs, such as facial expressions, body movements, and utterances. This skill is shared by almost all human beings beyond early childhood.

Nevertheless, these mental representations are not always correct; they might turn out to be wrong which would be referred to as “false beliefs.” This could happen for several reasons, such as an event having occurred without our knowledge. Thus, we can recognize that our belief was false, subsequently acquiring new information or updating our belief. This meta-representational ability allows us to realize that our beliefs can vary on the basis of the knowledge we have available (e.g., Mitchell and Laco  e 1991; Wellman 2017).

Although the philosophers have been discussing mind reading for centuries, it is only in the last 40 years that scientific research has focused on the intensive study of this topic. The term “theory of mind” appeared in scientific literature in 1978 when Premack and Woodruff published “Does the chimpanzee have a theory of mind?”. The authors defined ToM as the individual attribution of “mental states to himself and others (either to conspecifics or to other species as well)” (p. 515). In the same year, also Fodor (1978) published a philosophical paper on “Propositional attitudes” where he wrote about the “representational theory of mind.” The author considered the mind as “an organ whose function is the manipulation of representations and these, in turn, provide the domain of mental processes and the (immediate) objects of mental states” (p. 521). These three authors used the term “theory of mind” referring to a system of inferences, not directly observable states, which is used to make

predictions about the behavior of other beings. Soon the term appeared in developmental psychology (see Bretherton et al. 1981) where it became a common label in its field with the publication of the book *Developing Theories of Mind* in 1988, edited by Astington, Harris, and Olson. This book presented a special collection of empirical reports and conceptual analyses discussed in two important conferences which occurred 2 years before (i.e., in May 1986, International Conference on Developing Theories of Mind, University of Toronto, Toronto, and in June 1986, Workshop on Children's Early Concept of Mind, St. John's College, Oxford). Over the years this term has been used in a wide variety of ways that today is impossible to condense into a precise definition. Doherty (2009), for example, defined ToM as an "umbrella term" for children's understanding of mental states that are belief and desire.

After a definition of the theory of mind and its historical context, this entry will continue with a brief review of empirical research on the development of the theory of mind. Finally, it will consider the relation between ToM and the possible.

Research on ToM

"Do children have a theory of mind?"

A central issue in developmental psychology has been to understand how children begin to realize that they and others have mental states, which can sometimes be true – corresponding with reality – but may also be false. In addition, how and when children realize that these states of mind drive their actions and those of others (e.g., Baron-Cohen 1991; Lewis and Mitchell 1994; Moore 1996) are also fundamental. Investigating how a ToM develops could offer important insights into the study of social cognition. Several pieces of research have shown that by the end of their preschool years, at around 3–4 years, children have these skills and begin to understand that individuals might have false beliefs about reality (e.g., Astington et al. 1988; Frye and Moore 1991; Wellman et al. 2001; Whiten 1991). Furthermore, these skills are

universal because they are present in various cultures all around the world (Callaghan et al. 2005), and it seems that they are uniquely human because different adaptations of false-belief tasks have documented consistent failure in chimpanzees and other great apes (Call and Tomasello 2008).

One of the first and most famous false-belief tests for investigating ToM in children was used by Wimmer and Perner (1983). The authors made up different stories, acted out with dolls and props, such as the following: Maxi is a child who puts some chocolate into cupboard x. In his absence, his mother moves the chocolate from cupboard x into another cupboard y. Participants have to point to the cupboard where Maxi will look for the chocolate when he returns. Only when children are able to represent Maxi's wrong belief, which is "chocolate is in cupboard x," despite knowing that the chocolate is in cupboard y, will they be able to correctly indicate cupboard x. Wimmer and Perner (1983) found a strong age-based trend: the children began to pass the task at around 4–5 years (at this age level, however the majority of children pointed wrongly to the actual location y, while almost all 6–9-year-old children correctly indicated location x).

From the end of the 1970s to the end of the 1980s last century, we witnessed an increase in empirical investigations focused on the study of the ability to attribute mental states to others and its development from the second year of life (e.g., Baron-Cohen et al. 1985; Bretherton et al. 1981; MacNamara et al. 1976; Shultz and Cloghesy 1981; Shultz et al. 1980). New stories for the false-belief task were created or adapted from the original story. For example, Baron-Cohen et al. (1985) created another famous false-belief test, known as the Sally-Anne task. Sally and Anne are the two main doll characters in the story. After checking that the children know which doll is Sally and which is Anne (*Naming Question*), Sally first places a marble into her basket. Then she leaves the scene. At this point, Anne takes the marble out of Sally's basket and hides it in her own basket. Sally returns and the experimenter asks the child the key *Belief Question*: "Where will Sally look for her marble?". If the children indicate the previous

location of the marble – thinking that Sally believes that the marble is in her own basket – then they pass the Belief Question. On the contrary, if they point to the marble's current location, then they fail the question by not taking into account the doll's belief. Two further control questions confirm these conclusions if children answer correctly: "Where is the marble really?" (Reality Question) and "Where was the marble in the beginning?" (Memory Question). With these questions the experimenter could be sure that the child has both knowledge of the real current location of the marble and an accurate memory of the previous location (Baron-Cohen et al. 1985).

Although children younger than 4 years old usually fail these explicit tasks, it cannot be excluded that some less complex forms of understanding mental states develop earlier. Consequently, in order to investigate the precursors that anticipate the emergence of a more mature representational system, new empirical studies on infants' beliefs have demonstrated, in the last decade, a very early peculiar sensitivity to the false beliefs of others by using implicit looking-time tasks.

If infants are presented with a typical FB task with a change of location from box x to box y and the agent returning to the scene, infants usually show anticipatory behavior searching for box x and look longer when the agent reaches box y rather than box x; moreover, in true-belief control conditions in which the agents witnessed the object's transfer, infants show a reverse pattern, that is anticipatory searching for box y and longer looking times when the agent reaches box x (e.g., Baillargeon et al. 2010).

Many recent studies, which have investigated infants' looking behavior, suggest their ability to reason about other agents' false beliefs. However, it is important to highlight that there is considerable disagreement in literature over the question whether these results show that infants have a concept of belief similar to the one assessed by explicit tasks years later, as reported by Rakoczy (2012, 2017; see also Apperly and Butterfill 2009). Heyes (2014) provided a review of more than 20 experiments on infant false beliefs (e.g., Onishi and Baillargeon 2005; Senju et al. 2011; Song and Baillargeon 2008; Southgate et al.

2007; Surian et al. 2007; Surian and Geraci 2012; Kovács et al. 2010) and argued that positive findings reported by some of these studies are due to domain-general processes, for example, retroactive interference in memory for object location. The criticisms advanced by Heyes certainly open exciting avenues for new research aimed at understanding if infants are really able to appreciate others' states of mind.

ToM and the Possible

There is a very strong relation between ToM and the possible. ToM is based on the possible. When an adult or a child reasons about others' mental states, independently of their own true or false beliefs, they are thinking about the possibility that others could carry out specific behavior or reason in a certain way. Nobody has an absolute certainty about others' thoughts and feelings and sometimes not even about their own. Therefore, the possible plays a central role. To be aware that it is possible to consider a wide range of "beliefs" could enable us to be more functional in attributing mental states to others, also increasing our own mental flexibility.

The possible might be studied from different perspectives. Theories and research on the possible have focused on four key areas – possible worlds, possible selves, possible pasts, and possible futures (for a detailed description of these areas, see Glăveanu 2018). The theory of mind might be strongly linked in particular to the area of the possible selves. This area refers to conceptions of one's self in future states. It's an experience that leads a person, as an agent, through imaginative explorations in past or future situations (e.g., Erikson 2007; Glăveanu 2018; Zittoun and de Saint-Laurent's 2015). Obviously, we can extend this reasoning also considering not only possible selves but also possible others. All humans do not have a predetermined nature; they are beings open to the possible, at different degrees. Possible selves are strongly linked to possible others. The human self and, consequently, all the possible selves emerge from specific environments characterized by different social relations and cultural

resources. Within the boundaries that every being finds initially traced from birth and then, during development, might start tracing by themselves, an infinitive number of actions and interactions can offer specific forms of agency and ways of relating to possible others and forms others have to relate to a possible self (see also Glăveanu 2018).

Starting from these imaginative explorations, we could “construct an evaluative landscape of possible acts and outcomes” of selves and others (according to Seligman et al. 2013, p. 120). Below, we will try to apply an imaginative exploration of our false-belief tasks used to understand the theory of mind.

Consider the classical Sally-Anne task. What possible acts and outcomes can we imagine? The story recounts that Sally placed a marble into her basket and left the scene. Anne takes the marble out of Sally’s basket and hides it in her own basket. Sally returned and the key question is: Where will she look for her marble? The answer is that Sally believes that the marble is in her own basket. However, if we image several landscapes, different key questions and outcomes can come to mind. For example, consider some possible alternatives of Sally’s thought process: (a) the two baskets are identical, Sally does not remember which is hers (the marble is in any case in one of the two baskets); (b) Sally knows that Anne is nosy, and she could think that Anne had looked in her basket and had taken her marble to observe it better, so now the marble could be in Anne’s hand (both baskets are empty); (c) Sally knows that Anne is spiteful, she could think that Anne had moved her marble as a joke to the second basket (the marble is in the second basket); and so on. Endless different scenarios may be created by the imagination. The more different rereadings of the same scenario we are able to make, the better chance we have of understanding exactly what has happened, in particular when we refer to reality. Moreover, we can also consider all the possibilities of why Anne and Sally act out certain behavior. Why does Anne put her marble in the basket? Does she want to hide it, to keep it safe, to take it to someone or give it to them in the basket, and so on. Why does Sally move the marble to the second basket? Is it a prank, or to be spiteful (Sally

was angry with Anne), or is Sally bored and moves the marble just to fill in the time, and so on.

The combination of all the possibilities of decisions, intentions, and even emotions can generate an infinite number of different representations of reality. Experiencing self-other different perspectives offers individuals new views from which to understand and act on the world with flexibility, creativity, and imagination. This experience can significantly enact, increase, and define social interactions and communication, also increasing the well-being of oneself and others.

Summary

In the last few years, we have extended more and more our knowledge about how ToM works, its development, its neural underpinnings, and also about how it is affected by specific clinical cases, such as autism.¹ However, as Rakoczy (2017) highlighted, many different questions remain open for the future. For example, how do we develop from early implicit ToM to later explicit ToM? What are the neurocognitive foundations of ToM reasoning in infants and adults, and how do they change during development?

Furthermore, if we consider the ToM in relation to the possible, new exciting questions arise. What happens if we train people to a divergent way of thinking that considers all the other possible behaviors or mental reasonings? Will their theory of mind change? Will their affective responses, such as empathic responses, and rational judgments change regarding other behaviors and reasonings? Moreover, if people learn to analyze all possible alternatives before acting, they could learn to choose the best alternative for themselves and others. Increasing the consciousness of the variety of situations that the possible may allow people to start seeing the world not as it is, but as it could be, increasing their willingness to improve it.

¹For the sake of brevity, the relation between ToM and various other pathologies has not been included in this entry; for example, the importance of the ToM’s deficits in autism has not been covered; see Baron-Cohen (2000), Fletcher-Watson and Happé (2019), Mitchell (1997).

Keywords

Thought experiment · Imagination ·
Possibility · Epistemology of imagination

Overview

Thought experiments – like Schrödinger's cat and the trolley problem – are a way for inquirers to focus the power of the imagination. What makes a thought experiment different from fantasies and daydreams is that they aim to produce new knowledge, wisdom, understanding, illumination, or something like that. They typically also have a narrative structure, with a beginning, middle, and end. Usually there are several phases in a thought experiment: one in which we set up some imaginary scenario, another in which we “see” what happens in that scenario, and, finally, one in which we draw some conclusions. At this level of description, thought experiments are like laboratory experiments, except they are carried out in the imagination.

This entry will consider what thought experiments are, who performs them, how they have been investigated, what they aim to do, how they work, and how they connect to the possible.

What is it to be happy? Perhaps being happy is just feeling pleasure, like resting your legs after a long day's work, or listening to a favorite song. Robert Nozick presents a thought experiment to test this view (Nozick 1974). Suppose there was a machine you could enter, which would attach itself to your brain, and stimulate it so that you felt you were experiencing all the pleasures you've always dreamed of: the best food, fame, meaningful work, true love, etc. You would have no memories of entering the machine or of your previous life, and you must enter the machine for the rest of your life or not at all. Would you?

If pleasure is all there is to a happy life, we should all want to enter the machine. But the majority of people would refuse (Hindriks and Douven 2018). Why? Perhaps it is because there is more to happiness than pleasure. Maybe connections to real events and people matter too.

One thing that makes this a thought experiment is that when we begin, we don't know what will happen. We use our imagination, and we learn something new.

Here is another. Imagine a frictionless triangular prism with a chain draped over it, as in the picture below (see Stevin 1586, 183–187; Mach 1905).

How will the chain behave? Perhaps we think the chain will slide toward A or toward C. Okay. But now, what if the chain is connected around the bottom, like this?

Well, in this case, if the chain slides toward A, it will slide that way forever, and we will have a

perpetual motion machine. Same for C. In fact, the slightest motion in either direction will cause a perpetual motion machine. But perpetual motion machines are impossible. So then, what happens? The only other option is that the chain is still. In this case, there is no perpetual motion machine. But what, if anything, does this tell us about the first set-up, where the chain wasn't in a loop? Well since the link of chain at the bottom is a perfect semicircle, it exerts equal downward force on A and C. So removing it will not impact the balance of forces in the system. We therefore have the same balance of forces in both pictures. Thus, because the chain in the second picture must be still, the chain in the first picture must also be still. With this thought experiment, we've just learned something interesting about how chains behave when draped atop frictionless prisms in gravitational fields.

These are thought experiments. They are crucial for many disciplines, including philosophy, physics, engineering, and law. Paradigm examples in philosophy include Hume's missing shade of blue (and invisible gardener), Mengzi's child at the edge of a well, John Searle's Chinese room, Hilary Putnam's Twin Earth (and brain in a vat), Avicenna's falling man, John Rawls' original position, Frank Jackson/Daniel Dennett's color scientist, Judith Thomson's violinist, David Chalmers's zombies, Plato's cave (and Ring of Gyges), Donald Davidson's Swampman, and Philippa Foot's trolley problem.

Well-known thought experiments in science include Maxwell's demon, Laplace's demon, Einstein's elevator (and train), Schrödinger's cat, Isaac Newton's bucket (and cannonball), Heisenberg's microscope, Galileo's falling bodies (and pendulums, inclined planes, and ship cabin), the Turing test, and the prisoner's dilemma.

We find thought experiments in mathematics, especially concerning difficult concepts like infinity. We also find them in art. For example, philosophers have argued that *Huckleberry Finn*, *To Kill a Mockingbird*, *Oedipus Rex*, *Lolita*, *Henry V*, *King Lear*, *Hamlet*, *Animal Farm*, *Uncle Tom's Cabin*, *The Matrix*, and *2001: A Space Odyssey* all might count as thought experiments.

Thought experiments are also used in therapy to help people cope with phobias (Gendler 2004,

1160), in law to help judges make decisions (Maks del Mar [forthcoming](#)), in theology to help interpret scripture (Fehige 2018), and in computer science to help design morally responsible artificial intelligence (Awad et al. 2018). The only field in which thought experiments are claimed not to exist is chemistry (Snooks 2006), but this has recently been shown false (Stuart manuscript).

Definition and History

The term "thought experiment" was coined by Hans Christian Ørsted (1811) as a label to describe some of Immanuel Kant's work.¹ After Ørsted coined the term, the first seminal writing on the topic was Ernst Mach's in 1905. This drew the attention of Moritz Schlick (see Dohrn 2018), Alexius Meinong (1907), and Pierre Duhem (1914; see Buzzoni 2018a). In the 1960s, many of the most influential philosophers of science began to write about thought experiments, including Karl Popper (1959), Thomas Kuhn (1977), Imre Lakatos (1976), and Paul Feyerabend (see Arthur 1999, Stuart 2020).

The literature expanded greatly starting in 1986, the annus mirabilis of thought experiments (Fehige 2020). In this year, James R. Brown first laid out his controversial epistemology of thought experiments, and the first conference on thought experiments was held at the University of Pittsburgh (the proceedings were later published in Horowitz and Massey 1991). A number of important monographs and papers quickly began to appear, including Brown (1991a), Sorensen (1992), Häggqvist (1996), Gendler (2000), Kühne (2005), Swirski (2007), Ierodiakonou and Roux (2011), and Frappier et al. (2013). Historical studies have since been produced on, for example, thought experiments in the presocratics (Ierodiakonou 2005, 2011, 2018; Rescher 2005, ch. 4); Plato (Becker 2018); Aristotle (Corcilius 2018); Ibn Sina, Ibn al-Haytham, and Abu Hamid

¹ Similar notions (under different names) were in circulation before Ørsted. For example, we find some of these in the work of Georg Christoph Lichtenberg, Novalis, and Immanuel Kant (see Schildknecht 1990; Daiber 2001; Fehige and Stuart 2014).

al-Ghazali (McGinnis 2018);² Galileo (Koyré 1968; Palmerino 2011; Palmieri 2003, 2018); Newton and Leibniz (Arthur 2018); Kant (Buzzoni 2008, Fehige and Stuart 2014); Hegel and Wittgenstein (Westphal 2018); Ragnar Frisch (Herfeld 2019); Einstein (Norton 1991; Schlesinger 1996, 473–76); Maxwell (Krimsky 1973, Myrvold 2011, Stuart 2016a); Heisenberg (Popper 1959, Van Dyck 2003, and Camilleri 2007, Stuart 2016a); and many others. And now there are also broad, discipline-focused overviews of thought experiments in physics (Peacock 2018), biology (Schlaepfer and Weber 2018), politics (Miscevic 2018), theology (Fehige 2018), ethics (Brun 2018), economics (Schabas 2018), and mathematics (Starikova and Giaquinto 2018).

Despite all this, there is no agreement about how to define a thought experiment. As we will see, thought experiments have been characterized as fictions, arguments, models, intuition pumps, and much else. Geordie McComb claims that they are best conceived as having only a “family resemblance” in common with each other (2013).

So, there is no agreed-upon definition. But maybe we can define the *performance* of a thought experiment. This is the proposal of Tamar Gendler, who claims that performing a thought experiment is reasoning about a particular set of circumstances that are accessed via the imagination. It must have the purpose of confirming or disconfirming a hypothesis or theory. And the particular circumstance imagined must be more specific than the conclusion of the thought experiment (Gendler 2004, 1155).³ This last requirement is what gives thought experiments their *experimental* flavor: laboratory experiments derive general conclusions from specific circumstances and events, so thought experiments should as well.

However, there are thought experiments that pose questions rather than offer answers (like the Ship of Theseus⁴). And some thought experiments do not even pose a question: instead they aim only to illustrate a theory or theoretical claim (Brown 1991a, 32; Peacock 2018; Schabas 2018), “exemplify” properties (Elgin 2014), or provide “hypothetical explanations” (Schlaepfer and Weber 2018).

To make matters worse, there is also no agreement on how a thought experiment works. For example, some philosophers argue that a central feature of thought experiments is that they produce an intuition, which then serves as evidence for a claim (Brendel 2004, Brown 1991a, Dennett 2013, Mišćević 2018). Others disagree. For example, John D. Norton argues that thought experiments are just logical arguments, and thus whether they produce intuitions or not is largely irrelevant.

Perhaps we could proceed along the *via negativa* and try to distinguish thought experiments from what they are not. One obvious place to start is their context. Consider the following schema inspired by Brown (2007, 158)⁵:

Theory & Background → Mental Experience
→ Interpreted Result

Using this, we can distinguish between what Brown calls narrow and broad conceptions of thought experiments. On the narrow conception, the thought experiment is simply what happens in the mind: it is what we “see” happen in the imagination. It is not the background or the interpretation. On the broad conception, a thought experiment includes all of the above: it begins

²Did all of these people *really* conduct thought experiments? As James McAllister (2018) argues, the term “thought experiment” includes the modern Western concept of scientific experiment, which arguably did not exist before Galileo. When it is legitimate to attribute a thought experiment to a historical figure? This is an open question.

³Gendler’s definition takes elements from John D. Norton’s earlier definition (see Norton 1991, 129).

⁴According to Plutarch, Theseus returned to Athens on a ship. This famous ship became a tourist attraction, and had its planks replaced, one by one, as they decayed. The question is, if all the parts are replaced with new ones, is this still Theseus’s ship? If not, at what point does it cease to be the same ship? This thought experiment has developed over time, and there are now many more elaborate versions.

⁵Something like this distinction was first made by Hans Radder (1996) when discussing laboratory experiments. It was then applied to thought experiments by Sören Häggqvist (1996) and Tim De Mey (2003).

with the theoretical background and the question to be answered, includes the mental experience, and ends with an interpretation of the mental experience as an answer to our initial question. However, the cogency of this distinction would be rejected by those who hold that thought experiments are merely arguments (e.g., Norton 1996). On this view, all that matters for identifying a thought experiment are the premises, conclusion, and mediating inferences. There can therefore be no narrow conception of a thought experiment, because elements of background theory will be premises in the argument, and therefore they cannot be separated from the thought experiment without eliminating it. Likewise, the interpreted result is the conclusion of the argument, which also cannot be separated from the thought experiment.

In addition to the above disagreements, there is also no settled taxonomy of thought experiments. For some attempted taxonomies of thought experiments, see Popper (1959), Brown (1986, 1991a), and Boniolo (1997).

Because of these difficulties, some philosophers have judged it best to specify in advance a particular class of thought experiments they are interested in, in order to make more piecemeal progress (e.g., Häggqvist 2009, Cohnitz and Häggqvist 2018). Others try to use evidence about the use of thought experiments (e.g., in science or philosophy), to convince others that there really is a single nature or function for all thought experiments. We will focus on this latter strategy first.

One of the most discussed problems about thought experiments is how thought experiments are able to lead to new knowledge or understanding, despite not requiring new experience. James R. Brown's answer is that performing a thought experiment produces a new phenomenon in the mind (1986, 1991a, 1991b, 1992, 2004, 2007). This phenomenon can serve as "fairly conclusive" evidence for a theory (2011, 43).

John D. Norton (1991, 1993, 1996, 2004a, b) has been Brown's main foil. He argues that thought experiments are nothing but arguments. We gain new knowledge from thought experiments only by rearranging or logically extending

existing knowledge. For Norton, all thought experiments succeed or fail only insofar as they instantiate logically good arguments.

Several accounts attempt to mediate between Brown and Norton. These accounts all argue that thought experiments are more than mere arguments, but less than sources of knowledge derived from pure reason. Perhaps the most popular account is one that draws on cognitive science and was proposed independently by Nenad Mišević and Nancy Nersessian in 1992. The idea here is that thought experiments are "mental models." In other words, the narrative presentation of a thought experiment triggers the creation of a mental model, which is "a structural, behavioral, or functional analog to a real-world phenomenon" (Nersessian 2018, 311). The mental model is analogous to a real-world phenomenon in the sense that it accurately represents it, including the constraints on it. Mental models typically embed a specific and personal point of view, tend to be visual or quasi-visual, and are justified by drawing on embodied knowledge (Nersessian 1992).

Another account might be called "experimentalist." This kind of account focuses on the relation between thought experiments and laboratory experiments. Roy Sorensen (1992), postulates that thought experiments are on a continuum with laboratory experiments. For him, thought experiments perform one of the functions that laboratory experiments can perform, namely, finding and eliminating inconsistencies in our theories. Gooding (1992) emphasizes the embodied nature of thought experiments, in order to explain a sense in which they are like real experiments. And Stuart (2016b) argues that the epistemology of laboratory experiments can be used to evaluate the epistemic value of thought experiments: specifically, the principles for effective laboratory experiments can also be usefully applied to thought experiments. Finally, Marco Buzzoni has pointed out that there are different senses in which thought experiments can relate to laboratory experiments (Buzzoni 2008, 2018b): in one sense, thought experiments are necessary for laboratory experiments, because an imagined experiment must always precede a laboratory experiment. In this

sense, thought experiments are a condition for the possibility of laboratory experiments. On the other hand, experiments of all kinds ask questions to nature and attempt to provide answers, so in this sense, thought experiments and laboratory experiments are just the same.

There is also a fictionalist view of thought experiments (Meynell 2014, 2018; Salis and Frigg *forthcoming*). On this account a thought experiment is a fiction, and our role as thought experimenters is similar to the role of children playing a game of cops and robbers: we set some things as true in the fiction and use props to focus our imaginations. For example, in a game of cops and robbers, sticks might be guns, a set of rocks might be a jail cell, and if you are a robber and you are touched by a cop, you go to jail. The description of the thought experimental scenario plus some implicit or explicit rules of reasoning tell us what we must imagine and what we are allowed to do in the game. The rest is up to us. By reasoning through the imaginary scenario in accordance with the rules, we learn what else is true or false in the scenario. This enables us to learn from thought experiments, insofar as these tell us what things would be like in a given hypothetical world, which is significant because in some cases, that hypothetical world turns out to be the actual world. For example, in a series of famous thought experiments, Galileo asked what the world would be like if Aristotle was wrong about motion, and this enabled Galileo to make progress (since Aristotle *was* wrong).

Criticism of Thought Experiments

Some thought experiments seem too far-fetched to draw conclusions about the real world (Wilkes 1988). Some of them seem to promise necessary truth, which is something they might be unable to provide (Thagard 2010, 2014). They employ abstract situations, when what we often want are concrete details (Dancy 1985). And they rely on cognitive systems evolved for everyday scenarios, which can be inappropriate for complicated scientific systems (Bokulich 2001). For scientists these criticisms are more or less easily resolved, since

mathematical derivations and laboratory experiments can be appealed to when we want to settle disagreements. However, such recourse is not usually available for philosophers. Given that thought experiments appear to be a central part of the philosophical method, criticisms of the use of thought experiments must be taken seriously. The greatest modern challenge comes from what is called “experimental philosophy.” Beginning in the early 2000s, this movement has led to a methodological crisis that is still developing (for overviews see Knobe and Nichols 2017, Sytsma and Buckwalter 2016, Machery 2017, Stich and Tobia 2018).

Philosophers want to know about things like knowledge, love, happiness, and justice. They produce theories and test them using thought experiments. Experimental philosophers typically present short thought experiments to people, collect the responses, and analyze the data statistically. Some of the results suggest that the intuitions resulting from thought experiments are not shared among different groups of people, and they can be influenced by irrelevant factors including age, gender, culture, native language, level of education, religious belief, and ambient sights, smells, and sounds. We trust our vision because everyone agrees that an apple is an apple, regardless of age, sex, culture and sensory context. If we assume that the nature of knowledge, truth, justice, etc., are objective (like apples), then our intuitions about them appear only to reflect our subjective opinions, not objective facts (Sinnott-Armstrong 2008, 67; Stich and Tobia 2018, 374).

One response to this problem denies the diversity of intuitions. For example, a study by Machery et al. (2015) shows that intuitions about a particular thought experiment *are* shared by people in Brazil, India, Japan, and the USA, despite the fact that earlier studies claimed to show that they varied according to cultural context.

Another response has been to claim that intuitions resulting from thought experiments are informative, but only when the intuitions are *carefully considered* and when they are the intuitions of *experts* (Williamson 2007; Ludwig 2007,

2018). We should not be surprised that the intuitions that regular people have about quantum mechanics are easily manipulated; what matters are the intuitions of professional physicists. In reply, experimental philosophers have produced evidence that (they claim) shows that professional philosophers have corruptible and unstable intuitions too, even when it comes to philosophical topics (e.g., Schwitzgebel and Cushman 2015; Tobia et al. 2013; Schulz et al. 2011).

A third response to the challenge of experimental philosophy argues that the real job of philosophy is to tell us how we *should* characterize things. Thus, even if everyone had different intuitions about justice, this would not prevent us from fashioning a *better* concept of justice, one that people *should* possess. However, if philosophers still need thought experiments to generate and test their normative accounts, and these are fundamentally unreliable, the problem remains.

Experimental philosophy originally cast doubt on the use of thought experiments. But these days it also invents and employs its own thought experiments to identify new connections between philosophically relevant concepts. For example, here is a thought experiment created by experimental philosopher Joshua Knobe (2003) to test the influence of ethical judgments on attributions of intentionality:

The vice-president of a company went to the chairman of the board and said, 'We are thinking of starting a new program. It will help us increase profits, but it will also harm the environment.' The chairman of the board answered, 'I don't care at all about harming the environment. I just want to make as much profit as I can. Let's start the new program.' They started the new program. Sure enough, the environment was harmed.

Knobe asked participants whether the chairman *intended* to harm the environment. 82% of participants said he did. Now, and here is where it gets interesting, if you give the participants the exact same scenario but replace "harm" with "help," 77% of participants say that the chairman did *not* intend to help the environment. This result seems to imply that there is an important (and previously unrecognized) connection between ethical judgements and judgments about which

actions are done intentionally. This finding has now been extended from judgements about intentionality to judgements about what people want, desire, decide, advocate, oppose and know (see Pettit and Knobe 2009, Guglielmo and Malle 2010, Beebe and Buckwalter 2010).

In sum, thought experiments appear central to the methodology of philosophy, but their appropriateness and effectiveness have been challenged, and it is an open question how to respond. To muddy the waters further, the source of the challenge (experimental philosophy) now uses thought experiments as well.

Thought Experiments and Pedagogy

Because thought experiments are rhetorically and epistemically powerful, they are often used by educators. Their narrative structure, for example, makes them easy to remember. And the fact that they are open-ended requires students to think through complex issues on their own, which can stimulate learning and the development of new skills.

In support of claims like this, there are several social scientific studies which have been performed on students. Gilbert and Reiner (2004) found that students as young as 12 were competent with thought experiments. Others have shown that students resort to thought experiments on their own when faced with difficult conceptual problems (Köse and Özdemir 2014, see also Reiner and Gilbert 2000, 502). Thought experiments are used effectively by educators to elicit tacit beliefs (Reiner and Burko 2003, 380), to effect conceptual change (Helm et al. 1985), and to help students learn from performances of laboratory experiments (Matthews 1994). Yannis Hadzigeorgiou summarizes the general pedagogical benefits of thought experiments as helping students in (a) developing a creative imagination, (b) developing logical arguments and creative thinking, (c) developing problem-solving skills, (d) learning how to effectively modify laboratory experiments, (e) clarifying concepts, and (f) changing concepts (2016, 24).

This research on this topic is still growing, and there are many possible directions for it to go. For

example, are thought experiments equally useful in all fields and for all kinds of student? How do the spontaneously created thought experiments of young students differ from those of professional researchers? And are there ways to make educational thought experiments more effective?

Thought Experiments and the Possible

Thought experiments focus the imagination like telescopes focus light. This means that they connect to “the possible” in many of the same ways that imagination connects to the possible: by exploring possible worlds, possible selves, possible pasts, possible futures, and possible theories (see Glăveanu 2018). It is taken for granted by many philosophers that thought experiments can provide a window into the possible. For example, because Descartes can imagine that all of his beliefs are the product of a malignant demon’s deceptions, he takes it to be possible that this is the case.

Some argue that if we can imagine a scenario in some detail, this gives us a reason to believe that it is possible. However, we appear able to imagine impossible things. For example, it is easy to imagine things that are nomologically impossible (i.e., inconsistent with the known laws of nature, e.g., the gravitational constant being slightly stronger), although it is very difficult to imagine things that are logically or conceptually impossible (e.g., a circular square). Thus, some philosophers claim that imaginability should only be used as a *guide* to possibility, at best (Yablo 1993; Gendler and Hawthorne 2002). But why should it even be a guide?

This is an open question. Some argue that the mind evolved to imagine certain things accurately, because it benefited our early ancestors (Williamson 2016, Sorensen 1992). Thus our imaginations tell us whether and how fast we could climb a certain tree if a nearby wild animal were to charge, because that is something that could save our life. But in this case, we should expect our thought experiments not to be useful in telling us what a quantum system will do (Bokulich 2001). And yet many scientists use thought experiments to make great leaps of understanding concerning what is possible in very

“unintuitive” scientific systems, including quantum ones. One way to explain this is by reference to constraints: scientists learn the constraints on systems of interest, and they use these to constrain their imaginations in thought experiments (Kind 2018, 244). This might be a plausible explanation for many thought experiments, but not for those which purposely break reasonable constraints and still make scientific progress despite, or because of, breaking the constraints (Stuart forthcoming).

Another connection between thought experiments and the possible is a special use of thought experiments, favored by Kant, Hegel, and Wittgenstein especially, which we might call “transcendental” (see Westphal 2018). These thought experiments ask us to imagine something, and we find that we cannot. From our failure, we draw an inference about the limits of the human mind or our theories. For example, in his discussion of space and time, Kant asks us to imagine various things that are not in space or time. We can imagine space without objects in it and times in which nothing happens, but we can’t imagine, for example, an apple that does not exist in space or time. Kant uses this to conclude that space and time aren’t things in themselves, but concepts that we use to organize our experience (Critique of Pure Reason, A24-31/B38-46). Einstein does something similar with his chasing a lightbeam thought experiment against Maxwell’s theory of light (see Norton 2013). This kind of thought experiment is interesting because it uses our *inability* to imagine something as evidence in support of claims about the limits of our minds and conceptual frameworks, and perhaps also about the world itself.

Summary

Thought experiments are tools of inquiry that use imagination in order to gain insight. Through them, we seem able to get glimpses of how the world is, how it could be, and how it could not be. Philosophers, cognitive scientists, and social scientists are concerned with how they do this and what roles are played by things like logic, intuition, imagination, idealization, and images. Since they are a fundamental part of philosophical

methodology, the fact that they have recently come under scrutiny has been and will remain a central question until it is (re)solved. Some open questions include whether it's possible to give a satisfying definition or taxonomy of thought experiments, and how thought experiments relate to fiction, art, imagination, and emotion.

Tolerance of Ambiguity

Henderika (Herie) de Vries
Yale University, New Haven, CT, USA

Abstract

The present chapter aims to describe tolerance of ambiguity (TA) to make it more tangible, to disambiguate without reducing, and indeed expand the concept. The concept depends on and is shaped by perspectives related to cultural contexts, points to how humans relate to an immediate or distant future, and has emergent properties. TA seems to share meanings and properties with the concept of “Possibilities.” TA might in fact encompass both “Possibilities” as well as “Uncertainties,” representing two sides of the same coin. Broadly, all these concepts are found in the spaces between nature and humans’ relation with them. Above all, the TA concept is amorphous, abstract, and covers relationships with other concepts in a wide array of domains. Aspects are discussed in relation with existent literature, time issues, levels and lenses of research, and an application in the domain of creativity. Throughout the chapter, possibilities are suggested for further directions of research. Central to understanding and measuring TA is its cultural embeddedness, also of the researcher her/himself.

Keywords

Tolerance of ambiguity · Uncertainty · Culture · Measurement · Cultural actuation model · Creativity

Introduction

The concept of tolerance of ambiguity could perhaps best be explained with an analogy of a parable from the famous poet Rumi. Several persons tried to grasp the concept of an elephant by touching it in the dark (in Keshavarz 2007). Because everyone could only reach one part, and no one

could see the whole elephant, each one defined it differently. The inevitably limited human experience likewise could determine interpretations of the concept of tolerance of ambiguity (TA).

Consequently, each researcher and writer will approach TA from specific angles. TA can be described as an “essentially contested concept” (Gallie, in Levine 1985). Maybe the level of TA of individuals themselves also influences conceptualizations (De Vries 2018), which vary from suggesting there is no need to eliminate ambiguities, to arguing that, based on studies, tolerance of ambiguity does not exist (e.g., Kenny and Ginsberg, in Levine 1985). Scientists have for a long time attempted to fathom this elusive, but to all aspects of life-permeating, concept. There exist many definitions of TA today, and it generally concerns the levels of stress that individuals experience in the face of the unknown future, ambiguous information, and change.

Before diving into more theoretical aspects, it might be useful to make the phenomenon more concrete. Frenkel-Brunswik (1949) described TA as a “general social attitude which pertains to the whole being.” Many of today’s measurable psychological constructs did not exist then, and ought to be researched, in relation with TA. Furnham and Ribchester (1995) mentioned that TA can refer to individuals and also to groups. A logical question might therefore be: Can we observe TA, and what is the difference between individuals with high and low levels of it? In a portrayal of imagined (nonexistent) individuals from extremely high and low levels of TA cultures, Hofstede et al. (2002) described groups with low levels of avoidance of ambiguity and uncertainty (low avoidance = high tolerance) as groups having core values of “exploration” and “patience,” and individuals only adhere to rules that are absolutely necessary. What is different is perceived as curious, and generalists (not specialists) are valued. Words such as *maybe*, *spontaneous*, *unstructured*, *loose*, *relativity*, and *experiment* have a positive connotation. Words such as *structure*, *safe*, *predictable*, *tight*, *law*, and *duty* are seen as negative. Language use is soft (not loud), and unprecise, and high-level TA individuals often ask open questions. Nonverbal behavior is

marked by informality, by not being in a hurry, relaxedness, and having no taboos. Extreme low TA level individuals on the other hand exhibit a high need for certainty, and a preoccupation with truth. Rules are important, even if they do not work, and what is different is dangerous. Therefore, only familiar risks are accepted. There are rigid taboos of what is dirty, wrong, or indecent. Extreme low-level TA individuals argue a lot, are loud, quickly judge a situation as right or wrong, and are uptight. They externalize stress and make others feel stressed. The preference of language use is the opposite of that of highly tolerant individuals.

Overall, from a perspective of individuals with low levels of TA, individuals with a high level of TA, could also be described as being “wishy-washy,” as having no principles, and being pragmatic. The lack of structure is also visible through a certain fluidity or overflow. It is important to realize that without an understanding of the learned origin and therefore relativity of values and perspectives – considering there are no absolute criteria for measuring this either (Lévi-Strauss 1979) – both individuals with low or high levels of TA could wrongly be judged as negative, or positive.

Getting back to the scientific underpinnings of TA, although recent research has increased insight, there is still no consensus about its nature (Furnham and Marks 2013; Berenbaum et al. 2008; Jach and Smillie 2019; Hancock and Mattick 2020). Questions remain on how it relates to the Big Five personality traits, and other cognitive variables such as “need for closure” (Berenbaum et al. 2008). Researchers have also addressed the improved but still weak psychometric properties of self-measure scales of TA. For example, even one of the theoretically most robust scales of TA from Budner (1962) had a low internal consistency (0.49) (Furnham 1994).

Recently Merrotsy (2020) indicated again the need for research: “Since Frenkel-Brunswik in 1949, there has been sparse research conducted on its applications, in particular with respect to the study of ethnic and national cultures, of marketing, and of organisations, including business management and the armed forces” (2020, p. 647).

Merrot'sy's quote also demonstrates possibilities of domains where TA could have an impact. Many relations exist between TA and other concepts apart from authoritarian behavior (Adorno et al. 1950), the original motivation to develop the concept.

A domain where TA can be studied is creativity, interesting also because it is regarded as a main predictor (Stein 1953; Tegano 1990; Stoycheva et al. 2008; Tang and Chang 2010; Toh and Miller 2016). An example is a cross-cultural study of creativity and TA (De Vries et al. 2016; De Vries 2018, 2021).

Despite today's bulk of research, theoretical underpinnings of TA suggest that what is known today could still only be "minor parts of the elephant." This chapter will emphasize new possibilities to discover unknown aspects and dimensions of the concept of TA, rather than giving an exhaustive overview of TA literature. It addresses the origin of the TA concept, levels and lenses of research to explore, and the inherent time aspect related to the distinction between uncertainty and ambiguity. It further addresses measurement issues and relations with other concepts. Throughout this chapter new possibilities are mentioned of this "unitary, yet multifaceted" construct (Herman et al. 2010). The chapter is finalized with a summary.

TA Concept

Origin

The concept of TA can be traced back to philosophical, psychological, social, and organizational research roots. The philosopher Kierkegaard (1813–1855) mentioned that life itself is essentially ambiguous. Anxiety would be caused by the fear or "dizziness" of freedom because of life's ambiguities, which most people cannot bear ("Begybet Angst," or "The Concept of Anxiety," 1963). Later, empirical evidence confirmed a relation between TA and anxiety (e.g., Bardi et al. 2009).

Another example is last century's philosopher Fromm (1900–1980) who related religion to "existential angst" (Fromm, 2014). This is an

awareness of human freedom but at the same time also of the powerlessness before nature. In times as during a pandemic, humans might become more conscious of ambiguity and uncertainty, which according to Kierkegaard and Fromm is there at all times. Humans can embrace or escape freedom. Later, in "Ethics of Ambiguity", existential philosopher de Beauvoir (1947) described consciousness as ambiguous and that it limits humans' passion for meaning making.

The psychological research of Frenkel-Brunswik (1949) drew from psychoanalytical theory for the development of TA. It is fostered through the relationship children have with their parents. When parents are too aggressive, the naturally ambiguous feelings children have become repressed, and rigid thinking develops, which is now unintelligible, because it is based on obedience to dichotomized, external rules such as dominance-submission, clean-dirty, etc. and ambiguity is no longer tolerated. Frenkel-Brunswik further argued that TA impacts feelings, attitudes, interpersonal and social functioning, cognition, and problem-solving style as well as perception. This leads to the question whether researchers can explore more using today's possibilities to assess psychological constructs.

For example, how does TA relate to the malevolent personality traits of the "dark triad" (narcissism, Machiavellianism, and psychopathy [Paulhus and Williams 2002]) or "tetrad" (adding sadism) (Reidy et al. 2011)? How does social identity relate to TA (Stets and Burke 2000)? Another possibility to explore are Dabrowski's overexcitabilities (OE) 1967, the psychomotor, intellectual, sensual, emotional, and imaginal OEs. Some have already been studied in relation with TA. Examples are ambiguities related to senses like taste (Kolb 1995), and in listening to or composing music, and ambiguity in tempo perception (McKinney and Moelants 2006; Pressnitzer et al. 2011).

The origin of TA as it pertains to groups or societies is embedded in the definition of the cultural value dimension of uncertainty avoidance (UA) (Hofstede 1984, 2011), who defined it as the extent to which uncertainty and ambiguity are tolerated, and how unknown situations and

unexpected events are dealt with. UA is related to tolerance of the unknown future, caused by nature, other people, or transcendental forces. UA was derived from organizational theory (Cyert and March 1963). The Global Leadership and Organizational Behavior Effectiveness (GLOBE) project (Sully de Luque and Javidan 2004) interpret and use the concept of uncertainty avoidance in a slightly different manner. These authors measured “practices” and “values.”

More studies might also be needed on UA in general, as it is not completely independent of other dimensions (Minkov and Hofstede 2014). This raises the overall question if in today’s research the full breadth of the concept of tolerance of ambiguity is covered, and whether the interrelation of individual and group level of TA needs further clarification.

Interestingly, one of the earliest cultural philosophers, Simmel (1858–1918), already mentioned different levels of analysis in combination with differences of individuals’ naturally ambivalent tendencies. He mentioned how social interactions become a societal, structured phenomenon.

Conformity, individuation, antagonism and solidarity, compliance and rebelliousness, freedom and constraint, publicity and privacy, as so many sociological dualisms are compresent in social interactions and constitutive of various social relationships. These dualisms, [...] are inherent in social forms both because of man’s ambivalent instinctual dispositions and because society needs to have some ratio of discordant to harmonious tendencies in order to attain a determinate shape. (Levine 1985, p. 9)

As many cultural researchers have shown (e.g., Hofstede 1984, 2011; Schwartz 1992; Gelfand et al. 2011; Triandis 2018), societies organize themselves according to “different ratios of dualisms.” TA is also related to “conservatism,” one of Schwartz’s cultural dimensions. Gelfand’s and colleagues’ (2011) distinction between “tight” and “loose” societies has similarities to UA as in a higher or lower need of strict rules.

Something else, however, seems “hidden” in Simmel’s quote: There is a dynamic going from abstractness to concreteness. Human instincts are abstract, whereas societal values have a “determinate shape.” Because TA is related to *how* humans

interpret the world, there is an emergent property embedded in the concept as well.

Overall, the origin of the concept of TA is related to how humans exist in a naturally ambiguous environment, and was developed by philosophers, sociologists, and psychologists. There is a need today to further relate TA to new psychological constructs, explore new domains, and gain insight from different perspectives and on different levels of research, described in the next paragraph.

Levels and Lenses

To gain insight in the scientific concept of TA developed from different research domains, as with Rumi’s elephant, it helps to consider more levels and lenses of analysis. For example, within an empirical research tradition, besides an *individual* differences approach of TA and research on *societal* levels of TA, it could also be studied on an *organizational* level. An example would be the theory of “Murky environments” (Sternberg 2014). According to Sternberg, a new organization can cause uncertainty, be unclear and confusing, for people navigating it. A new school can, for example, represent a “Murky environment” also for a student who navigates it, to get good grades or make friends. Another example are astronauts on a space mission navigating in a “Murky environment,” when they navigate the organizational context in an unknown and extreme human environment.

Another possibility represents studying the *interrelation* and *interaction* of TA on different levels as with the uncertainty management theory, where interactions of uncertainty of a person, task, procedure of an organization, and the context are analyzed (e.g., Lind and Van den Bos 2002; Thau et al. 2009). This is based on the anxiety/uncertainty management (AUM) theory of Gudykunst (1995) and implies a principle of balance between two levels, a maximum and minimum level of anxiety/uncertainty that humans manage in interactions. Gudykunst et al. (1996) focused on causal explanations of social behavior and found individual values rather than cultural values to be a better predictor of behavior. Taking the study from Gudykunst one step further, Kam-Chung Chan

et al. (2004) defined dimensions of “interaction concerns” like “rapport promotion,” taking into account personal values, *situational* constraints as well as cultural values. Beghetto’s (2019) work on the related concept of uncertainty in educational contexts focusses specifically on uncertainty in structured *experiences*.

Sociocultural measurement of TA is based on theories that the psychological and cultural constructs “make each other up” (Shweder 1990). Rather than correlations between individual, interaction, and society levels, Gutiérrez and Rogoff (2003) describe *planes* and *lenses* of research. Culture is seen as a process rather than an influence, to be studied in “*repertoires of practice*,” or “*cultural scripts*” (Gorgorió and Planas, 2005). Sociocultural research into TA and uncertainty is still rare and mainly within the domain of science learning. For example, Kirch (2009) describes children doing science as identifying and resolving uncertainty as a mediated action by analyzing conversations. Metz (2004) examined “five spheres” of uncertainty derived from investigative procedures. Other interaction research is based on Berger and Calabrese (1974), as analyzing high uncertainty tolerance and intimacy in forming friendships (e.g., Redmond 2015; Knobloch and Miller 2018). Again, another example forms research describing how class *behaviors* and uncertainty might interrelate (Moran 2010). Concerning behaviors, Hofstede also found empirical evidence of levels of TA and behaviors in educational environments, organizations, and parental styles (Hofstede et al. 2005; Hofstede 2011).

Taken together the possibilities of investigating TA through different lenses and levels seems only at the beginning, and there might be many ways to investigate TA, or Rumi’s “elephant,” further.

Time Aspect: From TA to TAU

In an attempt to disambiguate TA, some scholars make a distinction between tolerance of ambiguity and tolerance of uncertainty, whereas others use both terms interchangeably. Some state that tolerance of ambiguity is a personal variable, and uncertainty avoidance a sociological variable

(e.g., Furnham and Ribchester 1995; Furnham and Marks 2013).

Grenier, Barette, and Ladouceur (2005) noticed about the relation of neuroticism and TA, that TA refers to a static component embedded in the present. Individuals are able or unable to tolerate a “here and now” ambiguous situation. Individuals that have no tolerance of uncertainty, however, would consider it unacceptable that a future and negative event may occur, even when there is only a small probability.

Other researchers argued that theoretically “the present” does not exist, that TA and UA represent the same, and simply represent a smaller or larger time difference (Minkov and Hofstede 2014). A more complete term would therefore be “Tolerance of Ambiguity and Uncertainty” (TAU). Although the time distinctions seem futile, time as it represents change, really is at the center for understanding the construct, and surveys of TA do not always include the time-related aspect of the “unknown close and distant future.”

Cultural differences in time perspectives are reflected in cultural values and could be seen as an evolutionary adaptation, related to group survival. In the animal world, time in relation to space is of the essence for prey organisms struggling against predators. This is how Jaensch (1938) indeed interpreted TA. He was probably, before Frenkel-Brunswik, the first to empirically isolate a predilection for ambiguity as a personality variable. Jaensch noticed that people differed in how stable their coordination in perception in relation to corresponding points of the retina of the eye were.

According to Jaensch, this stable personality type was preferable above the so-called “anti-type” that showed instable and “liberal” styles of perception and, in his opinion, cognition. For Frenkel-Brunswik, the opposite was true. She found a correlation between the authoritarian personality type and crude stereotyping, with rigid defenses and general lack of insight (1948). Therefore, she did not share the glorifying of Jaensch’s “unambiguous perceptual reaction personality type.”

In his book *The Open and Closed Mind*, Rokeach (1960) elaborated on the time dimension

of human beliefs and linked a narrow time perspective to dogmatic thinking, which concerns “systems of belief” (paradigms), instead of rigid thinking related to thinking within one system.

The knowledge aspect relates further to the “uncertainty principle” of Nobel prize laureate and physicist W. Heisenberg (1927/1930). According to Heisenberg, science is related to uncertainties of measurement, but also to humans’ understanding of and relation with nature, with concepts and language, and a human’s predisposition. Gaps of knowledge are determined by what is abstract and concrete, which varies according to different cultures.

TA is developed by learning norms, rules, and values of societies. The variation of societies in dichotomizing rules is related to the specific gaps of knowledge. The higher the level of TA, the more there is also a reduction of understanding of reality. A leader, for example, can symbolize values, and if followers adhere rigidly to these values, this then obscures realities, and ultimately can lead to dictatorships.

Overall, the time aspect is a central aspect of the TA concept, and it also determines if the concept of uncertainty is integrated, which can add to insights of related aspects of TA. A main original motivation of Adorno and Frenkel-Brunswik was how to secure peaceful societies, and to escape dictatorships. By emphasizing the time aspect and as a consequence integrate uncertainty as a component of TA, it is possible that more insight can be gained on this ever-important topic.

Measurement

TA is mostly measured through *self-report surveys* with items on attitudes (MacDonald 1970; Rydell and Rosen 1966; McLain 2009; Buhr and Dugas 2006; Dugas et al. 2004; Freeston et al. 1994; Greco and Roger 2001). Because of differences in definitions of TA, different measurement tools exist. Budner’s scale (1962), widely accepted also for its robust theoretical underpinning, for example, defines tolerance of ambiguity as “the tendency to perceive or interpret

ambiguous situations as a source of threat.” According to Budner, situations (or contexts) can be novel, complex, or insoluble. His “Intolerance to ambiguity scale” is based on philosophical principles. There is an intolerance when reality is altered to suit the desires of the perceiver. This can be done through (1) phenomenological denial (repression and denial), (2) phenomenological submission (anxiety and discomfort), (3) operative denial (destructive or reconstructive behavior), and (4) operative submission (avoidance behavior). Ambiguous situations are further distinguished as novel, complex, or insoluble. Despite the robust philosophical model, the Budner scale had a low internal consistency (0.49). It is interesting to notice that Budner’s model distinguishes a more cognitive (1), emotional (2), and action-oriented (3 and 4) facets.

In an ongoing attempt to clarify the concept of TA at the individual level, different researchers over time enhanced psychometric properties (e.g., Furnham 1994; Freeston et al. 1994; Buhr and Dugas 2006; Norton 2005). Furnham’s comprehensive content, as well as correlational and factor analytic study of four main TA questionnaires clarified some of the ambiguities of the construct. He discovered that the four most broadly used scales (Budner 1962; Norton 1975; Rydell and Rosen 1966; O’Connor 1952) consisted of multi-dimensional scales. Factors concerned, for example, tolerance of ambiguity related to preferences, anxieties, and philosophic and epistemological preferences.

Whereas scale items are mostly based on theory, the names to describe the factors mostly are not. As a result, comparing results of different analysis of found factors seems limited. Norton (2005) noticed that factors vary mainly with samples of different ethnicities.

Another issue is that most of the TA scales do not discriminate between different human functions as intended by Frenkel-Brunswik. The Budner scale and the TA scale of Greco and Roger (2001) are exceptions. Greco and Roger constructed their uncertainty response scale (URS) based on actual reactions (using a scenario technique) rather than using existing items or drawing them from literature. The result is a TA

scale consisting of emotional, cognitive, and desire for change (related to action) TA. An example of an emotional, cognitive, and change items are, respectively: (1) "When a situation is unclear, it makes me feel angry," (2) "I like to know exactly what I'm going to do next," and (3) "I think you have to be flexible to work effectively." An example of possible future studies are relations of emotional, cognitive, and action TA and different domains of creativity. Does the Nobel Prize laureate Bob Dylan (2016) have high levels of all aspects of TA? His music integrates emotions, philosophy in his literature, and action as during musical performance.

It could be that there are individual but also societal differences in emotional, cognitive, and action-oriented TA. Societal values are also related to how individuals think, act, and feel (Hofstede 1984). Could entrepreneurial performance be even more related to action-oriented TA (Teoh and Foo 1997)? Are low levels of UA (or high TA) found in the USA related to action-oriented and cognitive TA, but less to emotional TA? And inversely, does French society, found to score high on UA (low on TA), score higher on emotional TA (Minkov and Hofstede 2014)? Future research could explore these questions.

There are other aspects which can be distinguished concerning TA measurement tools. For example, according to Norton, intolerance of ambiguity is something that "manifests in situations," whereas for others it is a "general feeling" (Stoycheva 2003). For Norton, TA is "a tendency to perceive, or interpret information marked by vague, incomplete, fragmented, multiple, probable, unstructured, uncertain, inconsistent, contrary, contradictory, or unclear meanings as actual or potential sources of psychological discomfort or threat." (Norton 1975, p. 608). His MAT-50 questionnaire consists of 50 items drawn from literature and had a high internal reliability score (0.89). The eight domains were (1) philosophy, (2) interpersonal communication, (3) public image, (4) habits, (5) relation to work, (6) solving problems, (7) the social domain, and (8) artistic domain. An example of an item is: "I seem to enjoy parties most when I know most of the people there."

An example of a survey for children is the ambiguity tolerance scale from Stoycheva (2003). This original measurement consists of 14 items, half for intolerance and half for tolerance of ambiguity for children from 12 to 19 years old, which correlates well with Norton's scale. The items consist of very general feelings of ambiguity, for example, as in this item concerning intolerance of ambiguity: "You prefer the well-known certain things." Stoycheva's definition of TA is "To accept feelings of anxiety and psychological discomfort naturally provoked by ambiguity associated with new, difficult situations."

Next to self-report surveys, there are also assessment tools which focus on the *perception* of ambiguity, or ambiguity related to concrete stimuli. It is thought that mental imagery and saliency is required for the disambiguation of stimuli (Hodgson 2013; Slotnick et al. 2005). Another theory is based on the feature integration theory (Treisman 1998; Treisman and Gelade 1980). The visual system initially decomposes the visual world into maps of simple features such as color, orientation, and direction of motion. Through selective attention the visual system resolves ambiguities in neural coding that arises when multiple stimuli are processed simultaneously. This is the "Ambiguity Resolution Theory" (Luck et al. 1997). It concerns the visual system's physiology and anatomy.

Language use is also related to TA, which is seldom analyzed within a sociocultural approach. The linguist House (2006) conducted a number of studies on differences in communication styles of the German and English languages. She found that in German, explicit language is more used and related this to the cultural dimension of uncertainty avoidance. Another possible indicator of TA to explore could be language use related to time perspectives. Rokeach (1960) mentioned that humans can have a *broad or narrow time perspective* (overemphasizing or fixated on the past, or the present, or the future), which is related to resistance to change and anxiety, and dogmatic and rigid thinking. His studies showed that students with a narrow time perspective and rigid thinking favored the future tense in their stories and ended stories with a line projecting to the future.

Individuals with a narrow time perspective project into the future the outcome of events taking place in the present. Students with broad time perspectives did not write a last sentence to project into the future, but left stories open ended.

Concerning *behaviors*, apart from those already known (for an overview see De Vries 2018), an alternative approach to study TA could be through *embodied cognition*. Cognitions and physical movement are thought to be related, and over time shape pathways in the brain (e.g., Shapiro 2007; Glenberg and Kaschak 2002). Inhelder and Piaget (1964) believed that children first develop feelings of ambiguity at around 1 year of age, when they learn to walk. A (creative) cognitive process of Janusian thinking, related to TA, might also originate from around this moment in development (De Vries 2018).

Other cognitive processes during development could be explored in relation with TA. A study with children showed that having an immigrant background was related to producing ideas which were more “static” than containing processes (De Vries 2018). To describe a process, a “*hind-sight– foresight*” cognition is needed. Children were at the concrete cognitive developmental phase according to Piaget (1967) and therefore this indicates a possible relation with the “inversion reversibility operational system.” It is not known if training forward and backward thinking (as rewinding a movie) could enhance this cognition as well as heighten levels of TA.

Finally, uncertainty tolerance is recently also investigated using *neural and psychophysiological* correlates (for an overview see Tanovic et al. 2018). The heightened reactivity to uncertainty in intolerance of uncertainty is reflected in greater activity in the amygdala and anterior insula as well as startle and skin conductance responding.

The possibilities described above to measure TA are not exhaustive. So far research has found multiple dimensions, cultural differences, and a distinction between “cognitive,” “emotional,” and “action or change” related aspects of TA, and aspects according to abstract (general feelings), more process-oriented (as in situations), or concrete mechanical explanations (neural correlates). Instead of investigating TA itself, more can be

explored through correlation with other concepts, described in the next paragraph.

Related Concepts

On an individual level, there are relations with, but also distinctions from other psychological concepts, and research is ongoing. For example, concerning personality traits and intelligence, findings are contradictory. Berenbaum et al. (2008) found positive correlations with neuroticism and negative correlations with extraversion using the ten-item scale of the International Personality Item Pool. Berenbaum et al. (2006) found positive correlations with neuroticism and negative correlations with extraversion.

Using the Big Five Inventory-2 (Soto and John 2017) and an English-speaking sample ($n = 327$), Jach and Smillie (2019), however, find only partial correlations of TA and subfacets of “openness to experience.” They consist of subscales of intellectual curiosity, aesthetic sensitivity, and creative imagination. They also investigated the mediating effect of intelligence, measured with the International Cognitive Ability Resource (Condon and Revelle 2014). Regression analysis showed that openness to experience as well as extraversion significantly predicted TA, but not intelligence. The strongest connection was between the intellect aspect of openness to experience; the other subdomains were only related via intelligence.

Other researchers investigated boundaries of concepts close to TA. Mussel (2010), for example, studied how “epistemic curiosity” (e.g., Berlyne 1954) is related to other constructs, which were the “curiosity and exploration inventory” (Kashdan et al. 2004) “need for cognition” (Cacioppo and Petty 1982), “openness for ideas” (Costa Jr. and McCrae 1992), and “typical intellectual engagement” (Goff and Ackerman 1992). He concluded that there is no discriminant validity between a number of other constructs, and that these constructs highlight rather different aspects of the same construct, as 49–59% of the variance was shared.

Neighboring concepts of TA are: “need for structure” (Neuberg and Newsom 1993), “need

for precision” (Viswanathan 1997), and “need for evaluation” (Jarvis and Petty 1996). Often used in research in Eastern cultures, and cross-cultural research, is the related concept of “dialectical” and “paradoxical” thinking (Paletz et al. 2015).

Yet another example is the “need for closure,” studied in relation with TA (Berenbaum et al. 2008). It relates to a desire for definite, unambiguous, and certain knowledge, through “freezing” information too early, instead of questioning it (Kruglanski and Webster 1996).

Although it is generally found that TA is related to anxiety, some studies find only partial correlations (e.g., Berenbaum et al. 2008). Measured with the “Worry Domains Questionnaire” (WDQ) (Tallis et al. 1992) and the Intolerance of Uncertainty scale (IUS) (Buhr and Dugas 2006), these researchers found a correlation with all facets of TA, except for the subscale of “inflexible uncertainty beliefs.”

On the level of societies, UA is sometimes related to the distinction of “tight” and “loose” societies (Gelfand et al. 2011). Both concepts relate to a higher or lower need for written and unwritten rules, a need for predictability and structure, and resistance to change. Results of Gelfand’s findings, however, are opposite to UA results. This could be because Gelfand’s measure was based on national auto-stereotypes: Respondents in 33 nations were asked not to report their own values, beliefs, or emotions but to express their ideal for society. Someone can hold a negative stereotype, precisely because it is important to them personally. Also, Gelfand’s classification might be applicable to the organizational level instead of the societal level, but Hofstede’s UA also needs further validation to apply it to a society’s level, as there is not complete independence with the other cultural dimensions (Minkov and Hofstede 2014).

More issues could be discovered by applying TA to different domains. Referring back to Rumi’s elephant it is, for example, possible to ask if animals can display higher or lower levels of TA. Kaufman and Kaufman (2015) described creativity of animals, known to be related to TA. Are dogs more authoritarian than cats, do they have lower levels of TA? The next section

elaborates on human TA in the domain of creativity.

TA and Creativity

TA is currently widely applied in many domains, such as business, medical, and educational environments (for an overview see Furnham and Marks 2013).

A particularly interesting domain is creativity, because along with the personality trait “openness to experience,” TA is generally found to be a main predictor of creative performance (Tegano 1990; Furnham and Avison 1997; Comadena 1984; Sternberg and Lubart 1995; Stoycheva 2003, 2010; Zenasni et al. 2008, Kornilova and Kornilov 2010; De Vries 2018). Stein (1953), one of the first to theoretically relate TA to creativity, defined it as the individual being capable of “existing amidst a state of affairs in which he (or she) does not comprehend all that is going on but continues to effect resolution.”

Research is relatively sparse in this domain (Merrottsy 2020), and therefore there are many new possibilities. For example, it could be interesting to investigate creativity and TA levels of artists in high UA (=low TA) societies. The indigenous Australian aboriginal culture is thought to have one of the highest UA levels (Hofstede et al. 2005). Their art productions, “Jukurrpa,” seem to integrate both extreme high as well as extreme low levels of TA. On the one hand the representations are related to the “dream time,” or creation of the world, which transcends time, space, and reality, related to high TA. On the other hand, there are very strict rules for the artists, who each have a specific role in painting and color use from which they cannot deviate, as the dot-like paintings represent storytelling for land use and survival, related to low TA (Caruana and Caruana 2003).

Another topic could be the relation between TA and aesthetics. During World War II “ambiguous” arts of expressionists like Picasso were regarded as “degenerated” (*Entartete Kunst*) and forbidden (Steinkamp 2012). Ambiguousness was defined by, for example, not using colors

“correctly,” which had to be realistic, or when shapes and forms were contorted or abstract (e.g., unrealistic rectangulars), or when art was critical. Is there a relation with the TA level of the dictator himself as an aspiring artist of mainly realistic water color paintings?

A study with children on the relation of an artist’s own level of TA, ambiguity, and creative productions (De Vries 2018) revealed a relation between the level of TA of a person and features of creative productions. It appeared that individuals with lower levels of TA produced more ideas based on observable (surface) features. Individuals with higher levels of TA produced more abstract (core) ideas, or ideas containing a dynamic (process). Ideas consisting of “process” and “core” ideas were more original, thus more creative.

Moreover, there appeared to be cultural differences between children from different cultural contexts. As early as 9 and 10 years old, children in India, Russia, and Europe developed higher or lower levels of creativity according to these features. In India, for example, children produced more ideas based on observable features, compared to children in Europe where children produced more abstract and process ideas. In Russia children produced ideas consisting of all three features, which represented a high level of creativity.

These findings lead to the developmental “Cultural Actuation Model” (CAM) (Fig. 1, De Vries 2018, also see de Vries 2021 (supplementary material)). This model relates values of cultural contexts or environments, and the fostering of the development of specific kinds of creativity related to originality and fluency. It is in line with Frenkel-Brunswik’s theory on TA and uses the cultural value dimension of power distance (PD) (Hofstede 2011) because this dimension is related to hierarchy. There are cultural differences in authoritarianism of parental and teaching styles based on this dimension. Depending on the high, medium, and low levels of TA and PD, children develop creative potential marked by more or less fluency and higher or lower originality.

Thus, contexts and environments related to cultural values are conducive to different kinds

of creativity. A recent and similar model to the empirical research-based “Cultural Actuation Model” (De Vries 2018) is a theoretical model of constructs mapped on the “Space-Time Continuum” (Corazza and Lubart 2021), to investigate differences between intelligence and creativity. It will be interesting to discover more about the intricate relation between these two concepts because when TA is low children are not creative, but also, according to Frenkel-Brunswik think “unintelligibly.” It might be that in an extreme environment where time and space are tight, an individual (as opposed to a group) would need an extreme high level of TA to let go of any cultural limiting beliefs in order to survive.

A possible theoretical broadening could be imagined by integrating the concept of TA. For example, the “Space-Time continuum” describes “episodes” of creativity, suggesting there are moments of creativity. However, considering the emergent aspect of the concept of TA, the physical analogy with a “Wave Model” would become appropriate, graphically represented as a “waffle shape.” Creativity in this sense would be ever unfolding, and rises to the “surface,” where it becomes observable during “episodes.” Different kinds and contexts of creativity could then be related to certain frequencies and wavelengths, which are related to speed, and amplitudes related to originality. Furthermore, waves can collide, and the sum of waves could lead to constructive interference, or eminent creativity. Standing waves could be related to creative “flow” (Csikszentmihalyi 1997).

This example of applying TA to the domain of creativity indicates that future research in any imaginable domain or universe might lead to insights within these domains, while at the same time revealing new aspects of TA.

Researchers’ Bias

As mentioned in the beginning the concept of TA could be related to the level of TA of scientists themselves. This also implies the construction of measurement tools. From the study of TA in the domain of creativity, the cultural distinction of abstractness and concreteness appeared. Relating this distinction to existing measurement tools, it

Tolerance of Ambiguity, Fig. 1 “Cultural Actuation Model of Creativity” (De Vries 2018). Creative ideas can consist of one or more features: core, process, and surface features. Ideas containing process and core features are highly creative, whereas surface ideas are less creative.

A child can be raised in a high, medium, or low Tolerance of Ambiguity (TA) and Power Distance (hierarchical) environment. Children develop the highest fluency and originality in low PD and high TA environments (De Vries 2018).

could be that certain researchers focus more on TA items which are concrete, and others more on abstract aspects.

For example, Stoycheva’s PTATS measurement tool consists of very general, abstract, items. Norton’s MAT scale addresses dynamics

in situations, and related measures, such as “need for closure,” focus on concrete items to measure. There might be a cultural bias as to how to measure TA and this might explain part of the found weak psychometric properties, mentioned earlier, as well.

Minkov and Hofstede (2014) noticed that the concepts risk, fear, and anxiety, are sometimes used interchangeably. They remarked: *“However, risk is to uncertainty what fear is to anxiety: risk and fear relate to known acts and objects, whereas uncertainty and anxiety relate to the unknown; they are diffuse feelings”* (p. 164). Fear and risk relate to concrete “surface” terms, whereas uncertainty and anxiety represent abstract “core” feelings.

Furthermore, Heisenberg’s “Uncertainty Principle” states that the more is known of one property, the less precise another property will be. The principle is related to the paradigm that reality consists of probabilities and possibilities (as in quantum mechanics). A few centuries earlier, philosophers called possibilities uncertainties. Heisenberg could also have chosen to call his discovery the “Possibilities Principle.” Could his choice be related to his own lower TA level, a “need for precision,” or again a reflection of his cultural background? The TA concept should probably be expanded to “Tolerance of Ambiguities, Uncertainties and Possibilities” (TAUP), because it encompasses all these aspects.

Early on Heisenberg had the profound insight that concepts are related to personal predispositions and are culturally determined. Researchers should keep following Heisenberg’s vision, and reinterpret, transform, and synthesize concepts through intercultural collaborations. When discovering new aspects of TA, future researchers should address their own possible cultural biases in TA measurement.

Summary

The concept of TA originates from philosophy, and World War II spurred the development as a psychological construct. It is mainly applied in domains such as management, the medical environment, and creativity.

Research is conducted on various levels, such as the individual and cultural levels. Concerning the related cultural value dimension of uncertainty avoidance there is a validity problem to be solved. Construction of measurement tools based on

philosophy (Budner), or on actual reactions (Greco and Roger), reveal a possible distinction between cognitive TA, emotional TA, and action-oriented TA. Norton (2005) found cultural differences according to samples, which also needs further investigation.

The relatively little research on TA during the last decades offers possibilities to explore the concept further. Mostly researched as a cognitive variable, it should also be related to other psychological aspects such as Dabrowski’s over-excitabilities or the “Dark triad” of personality traits.

According to Frenkel-Brunswik (1949), parental rules and regulations, impinging from the outside, results in children’s naturally ambiguous emotions becoming rigid and thinking “unintelligibly.” Parental rules vary culturally, possibly causing gaps of knowledge in certain domains. Heisenberg theorized that gaps of knowledge are determined by what is abstract and concrete, which varies according to different cultures.

The developmental “Cultural Actuation Model” of creativity, in line with these theories, found that children at the ages of 9 and 10 refer more or less to abstract or concrete aspects of creative productions, and also differ in referring to processes (related to change). These differences are related to higher and lower levels of creative potential.

Overall, social environmental pressure results in determining what a society defines as “abstract” or “visible,” what can be perceived or not and relate to what is considered abstract or concrete. As a consequence, researchers who inevitably (and hopefully) are raised in a particular culture will also be influenced by the abstractness they have learned (or not), when constructing measurement tools.

The analogy with Rumi’s concrete “elephant” metaphor for the TA concept at the beginning of this chapter should perhaps be replaced not by the static “tip of the iceberg” metaphor, but rather a dynamic “top of the wave.”

The emergent property of creativity is reflected in the TA attitude of individuals, and researchers with a high level of TA interested in this topic

would, while embracing reality, stay curious towards infinite future possibilities. Could “riding the wave” be the best analogy for this fascinating concept?

Transdisciplinarity

Bem Le Hunte

TD School, University of Technology Sydney,
Sydney, NSW, Australia

Abstract

Transdisciplinarity is a practice that transcends disciplines and fields, extending the notion of what is known and knowable and what is possible to discover and create across, between, and beyond all our disciplines. As such, it is a practice that takes place in the emergent spaces between disciplines, which some writers believe is the future of discovery (Johansson F, The Medici effect. Harvard Business School Press, 2004). It is being hailed as a new way to tackle our most complex, networked challenges, yet it is also one of the most ancient ways of seeing the world as a connected whole, as evidenced by Indigenous cultures that do not separate their ethics from their geography, or their religion from their science (Yunkaporta T, Sand talk, how indigenous thinking can save the world. Text, Melbourne, 2019). It excludes no discipline, field, stakeholder, or country and is therefore described as an attempt at a unified field of knowledge – an inherently spiritual notion for some (Nuñez MC, Transdisciplinary Journal of Engineering & Science 2, 2011): “The keystone of transdisciplinarity is the semantic and practical unification of the meanings that traverse and lie beyond different disciplines” (Nicolescu B, Manifesto of Transdisciplinarity. Suny Press, 2002).

Keywords

Transdisciplinarity · Creativity · Complexity · Education · Transformation · Perspectives

It is proposed that transdisciplinarity is a discipline (Rigolot 2020) and yet by definition it must transcend all disciplines: (“trans” means beyond

or across). It empowers the student, researcher, or creator to consider the oceanic nature of knowledge and multiple perspectives, while making connections between knowledges to create new knowledge. In other words: “It occasions the emergence of new data and new interactions from out of the encounter between disciplines” (Nicolescu 2002). The researcher or learner cannot possibly comprehend the entire ocean of knowledge, and “an integrating synthesis is not achieved through the accumulation of different brains. It must occur inside each of the brains,” making it inherently transformative for individual participants. Knowledge, therefore, does not just exist *out there*, independent of the researcher. There are multiple knowledges, but only one “knower” whose role it is to integrate. The knower as “sense-maker” is integral to transdisciplinary practice, especially with complex, open-ended problems where there are no single, simple solutions. Sensemaking is a process that must be continuous and open to the past as well as future challenges (Weick 1995), and the sensemaker has to choose lenses or “frames” with which to see complex challenges, as well as re-framing the challenge(s) through a different disciplinary lens for greater insight (Dorst 2015). This re-framing serves to make the commonplace approach of a familiar method or discipline uncommon. Familiarity and over-reliance on a particular set of tools can reproduce more obvious solutions, and so an exploratory approach to mixing and mashing and inventing methods is often a more suitable means of transdisciplinary discovery than prescribed, formulaic, or template-driven approaches – a more abundant way to access the realms of the possible (Le Hunte 2020).

Problems with Disciplinarity

In some ways, transdisciplinarity is a reaction against a singular disciplinary approach to knowledge, which conjures up a rigid view of the world according to preconceived rules and truths, which are often culturally specific. While the word “discipline” is associated with study, “in fact the earliest known use of *discipline* appears to be

punishment-related; it was first used in the 13th century to refer to chastisement of a religious nature, such as self-flagellation” (Merriam-Webster.com 2021). The power of a discipline to punish students (with low marks) or reward (with high marks) is just one way that our disciplines continue to exert power over us. According to Foucault (2007), “there is no power relation without the correlative constitution of a field of knowledge, nor any knowledge that does not presuppose and constitute at the same time power relations.” So, understanding how we are “disciplined” may be something of a precursor to transdisciplinary work and the start of the critical thinking it entails – sometimes described as “learning to know,” which refers to continuous questioning of assumptions leading to continually “connected beings” (McGregor 2004).

If transdisciplinarity refers to an oceanic field of all knowledges existing together – diversity and unity combined – then the idea that this ocean can be divided up into disciplines may seem absurd to some. Louis Borges wrote *The Book of Imaginary Beings* where he attempted to create a fictional, novel taxonomy of life, dividing up the entirety of all creatures into bizarre categories such as “embalmed ones,” “those that belong to the Emperor,” “mermaids,” “those that tremble as if they were mad,” “those that from a long way off look like flies”. (Borges 2002). For some thinkers, this type of arbitrary fragmentation of the world simply reflects modern thought, which is accomplished at creating order “to tame the wild profusion of existing things” – and Borges’ fable simply serves to highlight “the exotic charm of another system of thought” as “the limitation of our own” (Foucault 2018). Others write that transdisciplinarity demands a decolonized approach, claiming that western disciplinary knowledge is “fragmented, specialized, linear and scientific” (potentially limiting the realms of the possible), and transdisciplinary knowledge is “one where the metaphysics of western understanding is questioned” (Gibbs 2018).

Transdisciplinarity is often confused with cross/multidisciplinarity where disciplines are combined and juxtaposed, but without a coherent

attempt to include and expand all disciplines. “From this stance, a root discipline (e.g., economics) may turn to several other disciplines to help it solve a problem...the intent is to serve the root discipline that initiated the collaboration” (McGregor 2004). It is also confused with interdisciplinarity, where different disciplines are assembled together, but “the people involved offer parallel analyses of parts of a problem” (McGregor 2004). In transdisciplinarity, many perspectives on issues are sought (from the disciplines and beyond) and the questions and issues themselves are re-framed as the disciplines re-align and negotiate how to serve a bigger cause. All of these approaches to knowledge explore different realms of the possible, each approach presupposing differences in intentionality, agency, and cooperation. Lattanzi, writing for UNESCO, uses the metaphor of a banquet to outline the differences: multidisciplinary is a banquet where everyone brings a dish. With interdisciplinarity, people might bring a dish with some sense of purpose (e.g., guacamole to go with beans for a Mexican meal). With transdisciplinarity, it is thought that everyone at the party plans and cooks and takes account of the entire context together.

Nobody can tell to whom the various elements belong and who composed them: the team-work has to be acknowledged. In the transdisciplinary banquet there is an optimal use of resources, as no dish is partially utilized, or just left over. There is an optimal concordance of tastes, as a great amount of time is spent in conceiving the many dishes in advance exactly with a view to their integrated fruition. The team-members acquire new expertise through their interaction. They improve their capacity of listening. They learn that they can produce a successful outcome, although they are not in possession of all the ingredients, neither are they familiar with all the cooking procedures. They understand that, when they are not doing the entire job - their entire job - they are paradoxically, all together, getting the job done. (Lattanzi 1998)

Why Transdisciplinarity Research?

If transdisciplinarity has evolved as an attempt to re-construct the wholeness of knowledge and the

intersection between fields, it has also arisen in response to the growing realization that our problems are more complex and connected than ever before, manifesting in “messy, social and physical contexts” that elude a mono-disciplinary response (Carew and Wickson 2010). These challenges that defy simple approaches are sometimes described as “wicked problems” (Rittel and Webber 1973). And as Einstein purportedly said, no problem can be solved in the context in which it arose. For example, there are potentially multiple contexts for addressing the problem of climate change, from educating girls to improving wellbeing in developing countries to promoting plant-rich diets (Drawdown 2021). Moreover, solving a problem in a single domain will often have unintended consequences in another. And simply by varying disciplinary lenses, wicked problems can be seen from multifarious perspectives. (A global pandemic will be seen differently through the lenses of medicine, business, policy, narrative, law, social sciences, etc., and combining these approaches will more authentically address the complexity of the problem as it arises, not simply as individual fields choose to see them.) Once again, a decolonized perspective on complexity might offer an important perspective – as Núñez (2011) writes: “From a transdisciplinary point of view, complexity is a modern form of the very ancient principle of universal interdependence.”

Quite apart from the global challenges and the importance of tackling them from multiple perspectives, transdisciplinarity serves the double function of opening up opportunities for research that are yet to be unveiled, as described below:

There are more questions to explore than ever before...so, for instance, you will find engineers collaborating with biologists to understand the toughness of the conch shell and applying it to everything from tank armor to auto bodies. Or you will see oceanographers, meteorologists, geologists, physicists, chemists, and biologists collaborating to understand the effects of global warming. New discoveries, world changing discoveries, will come from the intersections of disciplines, not from within them. (Johansson 2004)

How Is Transdisciplinary Research Conducted?

On the simplest, most crucial level, the transdisciplinary approach enables an oceanic vision of the world of knowledge, where no knowledge is out of bounds, and all knowledge exists together. While our Western institutions often limit the realms of what is possible in our discovery processes to only scientific Newtonian/Cartesian perspectives that slice up knowledge into measurable fields of research. Transdisciplinarity welcomes multiple ways of knowing, without necessarily privileging one over the other, expanding ways to access the possible through multidimensional participation in and through knowledge cultures. The disciplinary learner is agnostic, and must enter this liminal space (whereby there is no discipline or field) and they do this with others from different fields, ways of being and ways of knowing, often using multiple methods from across the disciplines.

Carew & Wickson offer a few principles follow that begin to encapsulate transdisciplinary research (Carew and Wickson 2010):

- 1) Firstly, transdisciplinary research involves “transcending and integrating” disciplines. It is not enough to cross boundaries, but the integration of knowledges is integral.
- 2) Methodologies must evolve through “inter-penetration of epistemologies” and “collaborative deconstruction.” Approaches must be reconciled, even though some believe certain disciplinary paths can never cohere.
- 3) There is a practical rather than abstract approach to tackling pressing social issue “within rich, contested real-world contexts”.
- 3) **Participatory**, including diverse stakeholders and those who would benefit from the changes.
- 4) **Innovative and experimental**, allowing ideas to be tested.
- 5) **Dynamic** and open to change in the face of new knowledges, discoveries and contexts (Riedy et al. 2018).

Transdisciplinarity “challenges numerous assumptions about research, including who does the research, where research is conducted, how outputs are valued, and how research is supported.” Moreover, the “relevance of the academic paper for research partners is not always shared,” which means outputs can include everything from policy briefs to documentaries, to comics and other Non-Traditional Research Outputs (NTROs). Breaking with conventions in an attempt to open up the possible can be challenging as well as being liberating. “To invoke Foucault, it is clear that there are systems of discipline and punishment at play when working in undisciplined ways”. Our funding system “favors and supports the hegemony of disciplinary research” and “working across different institutional and disciplinary cultures in university and policy bureaucracies requires structural change” (Patel 2019).

Why Transdisciplinary Learning?

It is suggested that transdisciplinary thinking skills are essential, simply due to the proliferation of disciplines and the inability to be an expert in all of them. “The number of disciplines increased from 7 (when first universities were founded in the 13th century), to more than 8000 in 2012. A great expert in a given discipline is totally ignorant in more than 7999 disciplines” (Nicolescu and Ertas 2008). Moreover, knowledge within those disciplines is more transitional than ever in our networked, rapidly changing world: “our science is a drop, our ignorance a sea” (Kerwin 1993).

While our societies are in rapid transition, it is said that today’s student might navigate up to 17 jobs across 15 fields once graduated (FYA 2017) – sometimes described as “portfolio

Riedy et al. (2018) propose (with some overlap) that there is no consensus even within their institution on what transdisciplinary research entails, but suggest that it should be:

- 1) **Purposive**, tackling a wicked situation and leading to positive change.
- 2) **Holistic**, engaging the “past, present and future of whole systems” while transgressing boundaries with regards to the site of research.

careers". Given that students are more often than not paying increasing fees for this education, there is a need to "future-proof" the preparation of a singular degree and "the ability to teach students to think creatively across disciplines could well become a moral and political imperative. In this context, further exploration of transdisciplinary creative practice is compelling" (Le Hunte 2019).

There is strong support from industry that creative competency in the face of growing complexity is perhaps the most vital skill our leaders can have, and that in-demand skills of the future include those taught in a transdisciplinary curriculum, such as complex problem solving, creative and critical thinking, and other collaborative skills (IBM 2010; World Economic Forum 2020).

Other writers have suggested that our education should prepare students for futures that are "radically unknowable" in the face of today's "supercomplexity," which "produces a multiplication of incompatible differences of interpretation." In this environment, the task of education is ontological (about being) not epistemological (about knowing) and "that the idea of skills, even generic skills, is a cul-de-sac" (Barnett 2012). In this sense, a transdisciplinary education offers "integral education of the human being." It is "an education which is addressed to the open totality of the human being, not to just one of the components" (Nicolescu and Ertas 2008).

Importantly, education is part of a complex system that cannot sit in a separate domain. In order to educate people for the major transitions we are encountering, we need today's learner to understand creative interventions into complex problems, because it is thought that we are stuck in old paradigms with limited, linear, siloed solutions to global challenges. The argument is that with wicked problems, "most actions, if they are eventually taken, tend to focus on back-end, shallow, reactive, short-term, single-factor, heavy-handed, de-contextual initiatives (like pesticides for pests and punishments for misbehavior in schools)" and a transformative, transdisciplinary education has been advocated as a solution (Wright and Hill 2020).

How Is Transdisciplinary Learning Conducted?

Transdisciplinary learning, by nature, requires students to explore a breadth of knowledge rather than the depths of knowledges. It tackles the entire taxonomy of unknowns through multiple lenses and methods. As it is impossible to conduct a transdisciplinary curriculum that addresses knowledge domains at depth, there might be a privileging of a Curriculum for Being rather than a Curriculum for Knowing – a focus on the knower, and how to learn and synthesize and discover, rather than a more content-driven monodisciplinary curriculum (Le Hunte et al. 2021, In press).

As such, it is inherently linked to transformative learning as once learners have had their worldviews expanded, it is hard for them to contract. This, in turn, may lead to "peak transformative experiences," which can entail shifts in worldview, consciousness, and self-awareness, leading to greater openness and inclusion and motivation to take action in the world (Le Hunte et al. 2021, In press). Indeed, transdisciplinarity has been compared to transpersonal psychology, in that the trans personal might be defined as "experiences in which the sense of identity or self extends beyond the individual or personal to encompass wider aspects of humankind, life, psyche or cosmos" (Walsh and Vaughan 1993). In this sense, it aligns well with Nicolescu's Mode 1 of transdisciplinarity as an "inner science." It becomes a "way of being" as it "extends far beyond the scope of research projects (Mode 2) and appears constantly and ubiquitously in real life" (Rigolot 2020).

Transdisciplinary learning is also inherently creative, as learning has to take place in the interstitial, liminal spaces between and beyond disciplines, in novel spaces where emergence and discovery has yet to take place. It challenges the traditional siloed approach to knowledge delivery as well as traditional theories of learning and teaching, such as constructive alignment (Biggs and Tang 2015), which requires the teacher to know in advance what will be learned, and does not hold space for unknown learning outcomes.

Instead, those who teach into transdisciplinary subjects discuss the need to “maintain a sense of wonderment in our teaching and to avoid developing a formula for it, which risks closing off opportunities for emergent outcomes. For staff, this openness can be a perpetual source of inspiration and rejuvenation, as students produce previously unimagined responses to complex challenges” (Kligyte et al. 2019).

As it is impossible to teach in-depth knowledge across every discipline, the focus leans towards creative discovery across, between, and beyond disciplines through in-depth problem-finding, problem definition, and solution-finding using methods from across a wide variety of disciplines as well as practices from industry, government, and community partners. As with transdisciplinary research, there is a focus on complex adaptive systems, systems thinking, and other theories that lend themselves to action, such as ideas for systems thinking, the circular economy (Kneese 1988), doughnut economics (Raworth 2017), etc. While there might be a strong focus on sustainability, these principles can be applied to any range of challenges that are situated in a context that is inherently complex. There might also be a focus on futures thinking, as transdisciplinary learning and research are naturally action-based, with an aim to create preferable futures from the complex “stuck-ness” of present challenges. And as most change-making ideas have an economic/financial co-efficient, there might be an entrepreneurial component to the learning, often with a deep consideration of social impact, unintended consequences, etc. (BCII 2019). All of these can also be seen as “probes” or interventions into complex systems, and some of them become “safe-to-fail” methods for shifting systems in a favorable direction (Snowden and Boone 2007). Needless to say, the above considerations require creative-thinking skills – the ability to think and design experiments, explore the “adjacent possible” (Johnson 2011), observe and understand the full context of a problem or opportunity being explored, and think critically and analytically beyond domains. These skills go well beyond popular, standardized processes such as Design Thinking, which imply the imposition of one

discipline on another – but rather require all the disciplines to work together, equitably. As well as familiarity with the goal of transdisciplinarity, learners are required to go deep into the various practices it includes – as well as values, empathy, and responsibility for the nonhuman world. This type of learning requires radical inclusivity and “presupposes an open-minded rationality” (Nicolescu 2002).

It should be mentioned that transdisciplinary learning does not take place simply in institutions, but often at the porous boundaries between worlds – students, academics, industry, government, and community partners and professional staff – as well as other participants in enquiry and learning well beyond. By including students as partners, without and outside of the traditional hierarchies, involving student voice and student input into and co-design of the curriculum, a kind of “third space” can be created, “enabling new relations and knowledges to emerge.” Transdisciplinary learning enables powerful mutual learning to take place (Polk and Knutsson 2008) in a way that enables further, broader emergence to take place.

Disrupting the way things are always done is a challenge for institutions attempting transdisciplinary learning. “For example, Scholz and Steiner (2015) argue that people who act within a system on a daily basis are experts on the contexts in which they operate. Integrating transdisciplinary... approaches allows us to further question power relationships implicit in traditional educational contexts” (Kligyte et al. 2019).

In spite of the potential of transdisciplinarity to transform society, one of the biggest challenges with learning beyond silos is that the average research and educational institution “favors and supports the hegemony of disciplinary research” according to Patel, writing for the Science Research Council (2019).

Features of a Transdisciplinary Curriculum

Constructing a transdisciplinary curriculum requires a different approach to learning and

teaching, with some of the following principles working together to promote discovery across traditional silos of knowledge (Le Hunte 2019):

- 1) The intentional curation of learning experiences that allow knowledges to combine well beyond the silos in which knowledge currently exists
- 2) The encouragement of creative leaps and connected thinking
- 3) An environment with agnostic (and respectful) attitudes to theories, methods, and practices
- 4) Creative constraints to contain and challenge the creative process (given that transdisciplinary knowledge is oceanic)
- 5) Slow thinking so students have time to “problematize” the fields they are exploring and negotiating and become comfortable with unknowns rather than rushing to obvious answers to complex challenges that have been trialed and failed before
- 6) Teaching students to ask better questions
- 7) The confidence to “not know” and the ability to overcome the “curse of knowledge” (Newton 1991)
- 8) Confident and creative teachers who can walk the talk and co-create a community of mutual learning
- 9) The introduction of creative mindsets and methods that encourage students to become change-makers and rule-breakers

Conclusion

Transdisciplinarity can be seen as a portal into the possible, as it encompasses all disciplines and delivers insight, discovery, and lessons between, beyond, and across all disciplines. Transdisciplinary education and research have some defining features. The practice (and it is very practical) might include:

- An ability to synthesize and discover knowledge(s) between disciplines, fields, industries, and communities with a creative intent and an openness to emergence
- An ability to tackle the real-world complex challenges of our time (with an intention to

move towards a more desirable future state) and to unpack and explore the connectedness of our systems for a better world

- The ability to value a diverse range of knowledge types, knowledge cultures, and ways of knowing, taking an oceanic view of knowledge and self that is holistic and connected to all systems
- An ability to combine knowledges with the lived experiences of diverse stakeholders to create communities of mutual learning

Behind these practices is a philosophical understanding that “fragmented thought” within any researcher or system is unable to create unity at a time when it is desperately needed (Nicolescu and Ertas 2008). And that transdisciplinary learning requires an ontological focus rather than an epistemological focus – a “Curriculum for Being, not just a Curriculum for Knowing.” As such, the transdisciplinary curriculum presents an integral, interconnected, transformative education of the whole being, to create empowered and creative thinkers with a sense of purpose. Ultimately, transdisciplinary learning and research present opportunities to travel between, across, and beyond every domain of knowledge – as well as strengthening an inner knowledge – building ontological capacity to meet the challenges of our time.

Transformational Creativity

Robert J. Sternberg

Department of Psychology, College of Human Ecology, Cornell University, Ithaca, NY, USA

Abstract

This entry presents the construct of transformational creativity – creativity that makes a positive, meaningful, and potentially enduring difference to the world. People who are transformationally creative seek to make the world a

better place. I first discuss creativity and then positive creativity, reviewing their strengths and drawbacks. Then I discuss three types of transformational creativity – fully transformational creativity, self-transformational creativity, and other-transformational creativity. I further discuss pseudotransformational creativity – creativity that is presented with the pretense of making the world a better place but that really is intended only to enhance the prospects of the creators. There are three types of pseudotransformational creativity – fully pseudotransformational creativity, self-destructive pseudotransformational creativity, and other-destructive pseudotransformational creativity. It has been a mistake, I believe, merely to teach for creativity, because so much of creativity has been put to bad uses. We should instead focus on teaching for the transformational creativity that makes the world better, not worse.

Keywords

Creativity · Transformational creativity · Pseudotransformational creativity · Positive creativity

So often, more is better. We tend to view higher levels of human abilities as a good thing. That is, we view more intelligence, more creativity, more musical talent, and more athletic ability – more of pretty much any ability – as better than less of it. But are these characteristics inherently a good thing? In particular, is more creativity (or intelligence) necessarily or somehow intrinsically a good thing?

On the one hand, having more of a desired characteristic, such as the characteristics above, would seem to be a good thing in that one can make contributions to the world that perhaps one could not make without them. On the other hand, there is no guarantee, or perhaps not even a probability greater than 0.5, that the contribution will be positive. As this entry focuses on creativity, let us use that as an example.

Historically, creativity has been used for some extremely positive ends. Creativity is at least in

part responsible for Beethoven's *Ninth Symphony*, Michelangelo's *David*, Kafka's *The Trial*, Darwin's theory of evolution, the electric razor with which I shaved this morning, the computer I am using to write this entry, and the cell phone by which I stay in touch with my children, which are a handful among the literally countless examples of creativity put to constructive use.

Some would say that creativity is naturally a positive force (e.g., Kaufman and Glaveanu 2021). I used to be one of them. For many years, I wrote about the value of teaching for creativity and teaching students how to think creatively (e.g., Sternberg 2010; Sternberg and Williams 1996). During that time period, I saw creativity, intelligence, and some other characteristics as intrinsic goods. After all, creative people have made the world what it is. What is there to complain about? But that was at a different time of my life and, as it turned out, of history.

Creative people have made the world what it is, but unless one puts on blinders, it is hard to ignore the negatives as well as the positives. Creativity has not only showed what is positively possible, but it also has showed us what is possible that is negative: weapons of mass destruction, machines that belch out carbon dioxide and methane that have produced horrific levels of global climate change; chemicals that have polluted the air and water; fascist and other propaganda; fake news disguised as accurate news that is designed to arouse the worst in people; social media-reinforcing clicks, even when the clicks result in people believing malicious falsehoods or buying harmful products; novel and politically useful means of surveilling, punishing, and assassinating political opponents; and deaths during the times of COVID-19 caused fairly directly by politicians who care more about creative ways to get reelected than about keeping their constituents healthy or even alive. Creativity, then, can be used cynically and destructively as well as it can be used constructively and with hope for a better future. The possibilities for creativity, then, are endless, but in neutral and negative ways as well as positive ways.

One can imagine a mirror that has two sides, one showing the positive sides of creativity, and

the other the negative sides. If one looks only at one side of the mirror, and conveniently has the other side facing a wall, one may see creativity as only positive or as only negative, or at least, as primarily one or the other. Rather, its possibilities are what we make of them. Intrinsically, creativity is neither positive nor negative. We might be tempted to think of creativity as positive – especially for those of us who have invested all or part of a career in conceptualizing, studying, and teaching it. But we do so only by closing our eyes and ears to all the negative uses to which it has been put.

A solution to the problem of the indifference of the construct of creativity to the uses to which it is put has been to distinguish among positive, neutral, and negative creativity (James et al. 1999; James and Taylor 2010; Sternberg 2021a, b, [in press](#); Sternberg and Chowkase 2021; Sternberg and Karami 2021). The idea would be that creative work is novel and useful. Positively creative work, though, is not only novel and useful, but also work that is put to a positive use. In other words, creative work that is negative in its uses or potential uses or even neutral is excluded from the category of positively creative contributions.

As so often happens in psychological research, what seems like a solution at one point in time comes to present the next problem at a later point in time. “Useful” does not always mean broadly positive. As my collaborators and I discussed the concepts of positive, neutral, and negative creativity, we kept running into three nagging problems. First, what is positive in the short run often is negative in the long run, and vice versa. Second, what is positive at one time in history may be negative at another, as the needs of society change over time. Third, what seems positive to some people or in other cultures often seems negative, or neutral at best, to other people or in other cultures. The differences may be cultural, or they may be simply a result of inter-individual differences. But the concept of *positive creativity* turned out to be much more elusive than we had expected it would be. Even within our relatively small and homogeneous research group, we had trouble reaching consensus as to what contributions were what. Many contributions had both positive

and negative aspects. Indeed, many of our examples even of neutral creativity turned out not truly to be neutral, but rather either ones on which people disagreed or ones for which there were both positive and negative aspects, which may or may not have canceled each other out.

Take 1: Positive Creativity

It was at this point that I realized that the construct of *positive creativity*, as we had conceived of it, was fraught with difficulties. Most contributions we came up with just did not neatly fit into any particular category of positive, neutral, or negative. For example, social media have been very positive in many ways, providing opportunities for people to communicate with each other at levels and in ways that never would have been possible before their advent; they also have provided news of importance that people might otherwise never learn about; and they further have provided people with a way to amplify their views and present them to a broad public that formerly would have been inaccessible. And yet, too much of the communication is hostile, aggressive, and even potentially damaging; the news feeds often are biased and sometimes deliberately so; the amplification of views may lead people to do incredibly stupid things, such as refuse to be vaccinated against COVID-19 because they believe the vaccines themselves cause the disease, or cause sterility, or contain microchips that are then permanently implanted in people’s brains. In our initial analysis, social media came out as an example of “neutral creativity,” but in a way that would be totally different from the neutral creativity of a novel and only slightly compelling design for a bowtie just brought to market.

Take 2: Transformational Creativity

Having seen that the concept of positive creativity was not accomplishing the purpose various creativity theorists and researchers had hoped it would serve, I introduced a different concept, transformational creativity, which derived from work

done on transformational leadership (Bass 1998; Bass et al. 1996; Bass and Riggio 2006) and later work done on transformational giftedness (Sternberg 2020a, b, 2021c; Sternberg et al. 2021).

Transformational creativity is defined as creativity that is deployed to make a positive, meaningful, and potentially enduring difference to the world (Sternberg 2021c) – to achieve a collective common good. Transformational creativity can be contrasted with transactional creativity, which is creativity deployed in search of a reward, whether externally or internally generated (Sternberg 2021c). The focus in the present essay is on transformational creativity and its various types. It is worth noting, however, that transformationally creative people may also be transactionally creative. That is, to accomplish their goals, they need to know how to “work the system.” But they differ from merely transactionally creative people in that their end goal is to effect positive transformation for the world, at some level. They may pick up salary, prizes, and various kinds of accolades along the way, but their ultimate goal is to improve the world. Note that not all transformationally creative attempts succeed as planned. Many drugs that have been introduced to improve people’s lives backfired, such as Thalidomide as a way of mitigating symptoms of morning sickness. The drug ended up causing massive birth defects.

Some transformationally creative individuals pay very high prices for their efforts. Malala Yousafzai was shot in the head. Socrates’ creative ideas led to his drinking poison because some of the more powerful citizens of Athens did not appreciate his work. Hungarian physician Ignaz Semmelweis proposed that physicians wash their hands in-between patients. He was mocked by most of his fellow physicians and suffered a nervous breakdown, ending in his being placed in an asylum, where he was beaten and ultimately died. Of course, there are also those who are amply rewarded during their lifetimes – Louis Pasteur, Albert Einstein, and even Nelson Mandela after years of hardship.

Transformational creativity can be of several different types. The two major types are genuine transformational creativity and pseudotransformational creativity. Transformational creativity

changes the world, at some level, for the better; pseudotransformational creativity is a pretense of changing the world for the better. There are three subtypes within each type.

An important question is whether what matters is the intention or the outcome. Whether something is transformational is determined by the outcome. But it is hard, although not at all impossible, to achieve the result unless one works toward it. The start is at least to try rather than to decide in advance that genuine transformation is a goal one cannot possibly achieve.

Genuine Transformational Creativity

Fully Transformational Creativity

The ideal type of transformational creativity, at least from the standpoint of the positivity and generality of its consequences, is *fully transformational creativity*. In this type of creativity, the creative individual seeks to benefit others as well as themselves through the application of their creativity. Often, they need to transform their own life before they transform the lives of others. Fully transformationally creative people discover fulfillment in their lives by changing other people’s lives. Often, they change their own lives as result of what they do for others. For example, Greta Thunberg will live knowing that her efforts at promoting climate change, whether or not they fully succeed, will have made a difference to the lives of young people like herself who previously felt unheard.

Self-Transformational Creativity

A second type of transformational creativity is *self-transformational creativity*. In self-transformational creativity, one uses creativity to improve, enhance, and enrich one’s own life. But the creativity one uses for one’s own life is not necessarily applied to anyone else’s life. One may have a hobby through which one tries to fulfill oneself and become the person one wishes to be – playing music, doing martial arts, painting, writing fiction, or whatever. In many cases, and especially for retired people who take up or return to a hobby, the goal is not to change the world for others, but rather, to change the world for oneself –

to find the kind of personal fulfillment and self-actualization (Maslow 1998) that may not be, and perhaps never has been, available through one's work or even one's interpersonal relations. Others may use religious practice for a similar purpose – to help them achieve spiritual fulfillment. However one does it, achieving self-actualization involves self-transformation but not necessarily transformation of anyone else.

Other-Transformational Creativity

A third type of creativity is *other-transformational creativity*. In this type, one transforms the lives of others, but not necessarily of oneself. Immigrant families sometimes come to a new country, for example, under challenging circumstances. The parents may have been professionals in their original country but find themselves in low-paying, working-class jobs in the new country – perhaps as taxi drivers or house-cleaners or operating the cash register in a convenience store. They realize they most likely have lost the opportunity for serious self-actualization in their own lives, but they devote themselves to creating for their children an environment that will enable their children to fulfill the children's dreams – and the parents' dreams for the children. Sometimes, the motives for other-actualization but not self-actualization are different. It can be a result of poor mental health. Some great writers, for example, such as Virginia Woolf, Ernest Hemingway, David Foster Wallace, Anne Sexton, and Hunter Thompson, contributed to others through their wonderful writings but then ended up taking their own lives before their natural time had come. Both Mahatma Gandhi and Nelson Mandela themselves led very challenging and challenged lives but contributed enormously to others. They transformed the lives of others but were less successful in transforming their own personal lives.

Pseudotransformational Creativity

Pseudotransformational creativity is creativity that is based on pretense. The creativity is presented as improving the world but makes the world worse. The creativity is actually for the selfish benefit of the person exhibiting it, and

perhaps their family, friends, and associates. This kind of creativity is regularly found in the political arena, certainly today in 2022. Pseudo-transformational creativity differs from self-transformational creativity in that the former is based on the pretense of helping others and is always deceptive at someone else's expense; self-transformational creativity is to make one a better, more self-actualized person and does not involve deception of others.

Fully Destructive Pseudotransformational Creativity

Fully destructive pseudotransformational creativity is the kind of creativity that is destructive of oneself and of others. It is the creativity of some modern dictators who, whatever their short-term gains, will be remembered in history as having sacrificed the well-being of the people they lead for their own ambitions, and for having harmed or destroyed the lives of their followers and opponents alike. Xi in China will be remembered for having installed in China a 1984-like surveillance state, complete with concentration camps and mind control, that deprived millions of Chinese of anything resembling freedom of thought and action. Vladimir Putin in Russia will be remembered for what – invasions of neighbors? Novel assassinations and assassination attempts? Reinstalling in Russia the corrupt autocracy that some had hoped would go away with the end of Communist rule? Would-be dictators such as Trump in the United States or Bolsonaro in Brazil will be remembered for what – their narcissistic attempts to retain power, even at the cost of the countries they have led? In each case, their gain is through deception and at the expense of those for whom they are supposed to be responsible.

A serious problem with fully pseudo-transformational creativity is that the purveyors of it tend to be both charismatic and narcissistic, and such toxic leaders are appealing (Lipman-Blumen 2006), as they always have been, to uneducated people who are taken in by appeals to their victimhood, and to colluders who see a chance in followership of these leaders for personal gain at other people's expense. Thus, toxic

leaders often do not always have to force themselves on others; they may well be chosen by those ready to be taken in by toxic appeals.

Self-Destructive Pseudotransformational Creativity

Self-destructive pseudotransformationally creative people do themselves in by their own creativity. They may be terrorists, insurrectionists such as at the US Capitol building on January 6, 2021, or users of social media who are self-destructive in their attempts to destroy others. In a sense, they call to mind Sigmund Freud's concept of Thanatos – of the forces within all of us that lead to our own destruction. They are likely to be people who would like to harm others but are too inept or too focused on themselves ever to get the chance.

Other-Destructive Pseudotransformational Creativity

Other-destructive pseudotransformational creativity is aimed solely at others and spares the purveyor of the destructive creativity. Internet swindlers, spammers, poison-pen social-media contributors, and propagandists often attempt to change things in a way that will be harmful to others but that will spare them. At the time I am writing, they are often succeeding, at least in the short-term. The policing capabilities of the Internet, of social media in particular, and of other aspects of modern life are so behind the capabilities of malefactors that it is hardly a contest.

Conclusion

Educational systems often ignore creativity or may actively discourage it. Multiple-choice tests, for example, which are so common in the United States and many other countries, are poor instruments for measuring or encouraging creativity. But creativity, in itself, is as likely to be used for ill as for good. The concept of positive creativity was introduced to help steer things toward positive ends. But a limitation of this construct is that what is positive – or useful in a positive way – for one individual or group may

be negative for another individual or group. For example, Republicans and Democrats in the early years of the third decade of the twenty-first century in the United States seem to have very different ideas about what is positive and what is negative creativity. A 2021 law passed in Texas that has seemed to bypass federal abortion statutes was creative – in assigning responsibility for enforcement to vigilantes – but whether that is positive or negative depends on one's point of view. Transformational creativity is creativity that makes the world a better place. It should transcend special-interest groups. It should generalize to broader issues. If the Texas law, for example, encourages vigilante justice and spying on neighbors, is that what people want for other aspects of society? Do they want to become a modern-day post-World-War II East Germany? Or a modern-day China? Will we have vigilante justice for perceived political transgressions as well? How about ones that any particular group sees as matters of morality, such as sex before marriage? Is the "possible" of the future a surveillance state with a top court representing a political party and masquerading as meting out impartial justice? Is it a political party that takes over by minority rule?

We should develop fully transformational creativity in youngsters. The matter is not a trivial or even a small one. In contemporary society, much of creativity, although certainly not all, is being used for bad ends. More creativity may be better, or it may not be. Idealism about the concept of creativity will not stop the road toward the possibility of a dystopian future. Transformational creativity might.

Transformative Cognition

Andrea Gaggioli

Department of Psychology, Università Cattolica del Sacro Cuore, Milan, Italy

Applied Technology for Neuro-Psychology Lab, I.R.C.C.S. Istituto Auxologico Italiano, Milan, Italy

Abstract

Personal change is generally considered as a gradual and linear process, which occurs either as a result of maturation over the lifespan or as the result of a therapeutic interventions. However, research from different disciplines – including anthropology, philosophy and psychology – suggests the existence of a second type of change – transformative or transformational – which involves a radical and long-lasting shift in the individual's core beliefs, values, and attitudes. In this contribution, I will review key definitions and conceptualizations of transformative experience, discuss the scientific and practical relevance of this construct, and suggest some future directions for research.

Keywords

Personal change · Transformation · Transformative change · Cognition

Introduction

The famous short novel by Charles Dickens, *A Christmas Carol*, tells the story of Ebenezer Scrooge, a greedy, cold-hearted, and selfish usurer in the City of London who disparages charity and suggests that the poor should die. On Christmas night, he meets three ghosts: the spirit of the Christmas Past, the spirit of the Christmas Present, and the spirit of the Christmas Yet to Come. The three ghosts will retrace Scrooge's existence, showing the misery of his present and what will happen in the future (he has died, and no one misses him) if he does nothing to change. After these encounters, Scrooge wakes up on

Christmas' Day with a new outlook on life, grateful for being given a second chance.

As noted by Miller and C'de Baca (2001) in their seminal book, *Quantum Change: When Epiphanies and Sudden Insights Transform Ordinary Lives*, Scrooge's life-changing encounter is a prominent example of a transformative (or transformational) change: an experience that generates a profound and enduring alteration in a person's beliefs, values, assumptions, and preconceptions, leading to the construction of new meaning in life. Anecdotal accounts of transformative change are found in a number of historical biographies and in the popular culture, which abounds with tales of heroic transformation that are transmitted to countless generations throughout the ages (Allison et al. 2019).

Surprisingly, despite its cultural relevance, the phenomenon of transformative change has not been systematically investigated from a scientific perspective. One possible reason for the scant research on this topic is that, within the psychological field, change is generally regarded as a gradual and linear process, which occurs either as a result of developmental changes that happen over the lifespan (from birth to death) or as the effect of counseling and psychotherapy interventions (McDonald 2008; Kottler 2014). However, increasing evidence from across disciplines suggests that the process of change is not always incremental and can also occur in discontinuous and nonlinear ways, although not necessarily instantaneous (Hayes et al. 2007; Skalski and Hardy 2013). Furthermore, a considerable body of research has recognized the clinical significance of transformational change and its potential healing effects (C'de Baca and Wilbourne 2004; Kottler 2014). In reviewing this literature, I will show that personal transformation is essentially a process that allows individuals to explore new spaces of possibilities for thinking, feeling, and acting, by providing novel lenses or frames through which understanding themselves and reality.

Transformation versus Change

William James was among the first psychologists to explore the nature of life-changing experiences.

In his great classic, *The Varieties of Religious Experience* (James 1902), James analyzed the phenomenon of conversions and their moral implications. As he observed: "Whenever one aim grows so stable as to expel definitively its previous rivals from an individual's life, we tend to speak of the phenomenon, and even wonder at it, as a transformation" (James 1902, p. 70). James was especially interested in conversions that are manifested as sudden, dramatic, and unexpected. Most of the examples of conversions that James reports in his book are characterized by a sense of regeneration and a deep alteration of character. James stressed that intense **emotions** play a significant role in shaping conversions: "Emotional occasions, especially violent ones, are extremely potent in precipitating mental rearrangements. The sudden and explosive ways in which love, jealousy, guilt, fear, remorse, or anger can seize upon one are known to everybody. Hope, happiness, security, resolve, emotions characteristic of conversion, can be equally explosive. And emotions that come in this explosive way seldom leave things as they found them" (pp. 184–185).

About one century after James' work, psychologists William Miller and Janet C'de Baca (2001) introduced the concept of "quantum change" to describe "a vivid, surprising, benevolent, and enduring personal transformation" (p. 4). The authors used the adjective "quantum" to emphasize the peculiar character of this process of change, which is linked with an identifiable, distinctive, and memorable experience during which the transformation occurred, or at least began. According to Miller and C'de Baca, such experiences are usually very vivid, allowing individuals to recount them with a great deal of detail. The element of surprise is related to the extraordinary and unexpected nature of the experience. For these authors, a transformative experience is also characterized by a profound benevolent quality: although the event can be immediately perceived as unsettling and destabilizing, it tends to be associated with a feeling of goodness and overall positivity. The final distinctive feature of quantum change is that its effects are enduring. In Miller and C'de Baca's own terms, it represents "a one-way door through which there is no going back"

(p. 5). Drawing on the analysis of dozens of stories from interviews and questionnaires collected from participants in New Mexico, Miller and C'de Baca identified two types of quantum change: the "insightful" type and the "mystical" type (Miller and C'De Baca 1994, 2001). **Insightful** changes are described as breakthrough of internal awareness, such as those occurring in psychotherapy. These are "a-ha" experiences in which the person comes to a new realization, a new way of thinking or understanding. **Insightful** transformations grow out of life experiences, in that they tend to follow personal development. By contrast, mystical quantum changes are akin to James's (1902) religious conversions, involving altered state of consciousness and intense feelings of awe; in Miller and C'de Baca's own words, "They flood the person's thinking and feeling processes in such an intense manner that it is though the person is being redesigned" (p. 72).

Jarvis (1997) introduced the concept of *epiphanic experience*, defining it as "one of sudden discontinuous change, leading to profound, positive, and enduring transformation through reconfiguration of an individual's most deeply held beliefs about self and world." McDonald (2008) described epiphanic experience as "sudden and abrupt momentary insights and/or changes in perspective that transform permanently the individual's concept of self and identity through the creation of new meaning in the individual's life" (p. 90). According to McDonald, epiphanies are momentary experiences of transcendence characterized by a peculiar profile that distinguishes them from other types of developmental change and transformation, including the following core features: (a) antecedent state: epiphanies are often characterized by periods of anxiety, depression, and inner turmoil; (b) suddenness: they are sudden and abrupt; (c) personal transformation: epiphanies are an experience of profound change; (d) illumination/**insight**: epiphanies are an acute awareness of something new, something that the individual had previously been blind to; (e) meaning-making: epiphanies are profound **insights** because they are deemed significant to the individual's life; and (f) enduring nature: although the actual epiphany is a momentary

experience, the personal transformation that results is permanent and lasting.

According to Jack Mezirow (1978, 1991, 2000), transformative learning is "the process by which we transform problematic frames of reference (mindsets, habits of mind, meaning perspectives) – sets of assumption and expectation – to make them more inclusive, discriminating, open, reflective and **emotionally** able to change. Such frames are better because they are more likely to generate beliefs and opinions that will prove truer or justified to guide action" (Mezirow 2003, pp. 59–59). The basic tenet of Mezirow's framework is that people view and understand life experiences through specific "frames of reference," which are sets of fixed assumptions and expectations encompassing two dimensions: "habits of minds" (i.e., habitual ways of thinking, feeling, and acting influenced by assumptions that constitute a set of social and cultural codes) and "point of views" (i.e., how these assumptions are expressed). Existing frames of references filter and limit future learning opportunities, since people tend to attribute old meanings to new experiences through them. Crucially, individuals can change these meaning schemas if they engage in critical reflection on their experiences, eventually leading to a perspective transformation. Mezirow holds that an individual might go through a transformative learning experience when faced with a "disorienting dilemma," which challenges existing habits of minds and require the person to critically examine them. For Mezirow, a disorienting dilemma is usually triggered by a life crisis or major life transition (e.g., death, illness, separation, or divorce), but it can also result from "an eye-opening discussion, book, poem, or painting or from efforts to understand a different culture with customs that contradict our own previously accepted presuppositions" (p. 168).

Mezirow argues that critical reflection plays an essential role in the transformative learning process and identifies three types of reflections that can occur when people face a dilemma: (i) content reflection, (ii) process reflection, and (iii) premise reflection. The first two are involved when we reflect on the content of an actual issue (i.e., "what are the key issues to examine?") or on the

process by which we solved a specific problem (i.e., “how did I get here?”). These areas of reflection result in the transformation of meaning schemas, which is a common, everyday occurrence. In contrast, premise reflection concerns the relevance of the problem itself (i.e., “why did this happen?”) and involves a critique of the pre-suppositions on which our beliefs have been built. According to Mezirow, premise reflection can bring about the most significant learning, as it results in the transformation of one’s overall meaning structure.

Which Experiences Are Transformative?

Although in principle all experiences have the potential to change us, we intuitively know that not all experiences bear the same transformative potential. According to the philosopher Laurie Paul (2014), an experience can truly change us if it is both *epistemically* and *personally* transformative. Paul argues that an experience is epistemically transformative when it allows an individual to grasp new knowledge that would be inaccessible to the knower until he or she has such an experience: for example, seeing a color for the first time. However, there are experiences that not only teach us something totally new, but that are also able to change our point of view and core preferences: for example, the experience of having a child not only provides new knowledge about what is like to have a baby, but it can also change a person’s values, priorities, and self-conception in ways that are deep and unpredictable. For Paul, personally transformative experiences can be of various natures, such as “(experiencing) a horrific physical attack, gaining a new sensory ability, having a traumatic accident, undergoing major surgery, winning an Olympic gold medal, participating in a revolution, having a religious conversion, having a child, experiencing the death of a parent, making a major scientific discovery, or experiencing the death of a child” (p. 16).

Paul’s definition of personally transformative experiences points to the important question of whether *positive* personal transformation can be originated by also potentially disruptive life

events, such as a major illness, the loss of a significant other, or natural or social catastrophes such as earthquake, tsunami, war, and terrorism. The posttraumatic growth model, developed by Calhoun and Tedeschi (1998), Tedeschi and Calhoun (2004), offers an affirmatory answer to this question, suggesting that even traumatic or highly stressful events can be a source of personal development. According to Tedeschi and Calhoun, changes in the aftermath of crisis can occur in five general domains: appreciation of life (having an increased appreciation for life in general), social relationships (having more meaningful and deeper interpersonal relationships), personal strength (having an increased sense of personal strength, feeling stronger than before), new priorities (having changed priorities about what really matters in life), and spirituality (having an enhanced sense of spirituality, feeling connected to something bigger than oneself (Calhoun and Tedeschi 1998; Tedeschi and Calhoun 2004). The authors argue that a devastating event or a major life crisis can trigger a complex set of cognitive and **emotional** processes which lead to a reassessment and reconstruction of an individual schemas, goals, and beliefs. According to Tedeschi and Calhoun, this meaning-making process can foster the development of new life **narratives** and **insights**, eventually leading to higher levels of satisfaction and psychological well-being.

The posttraumatic growth model focuses on the potential positive changes following highly stressful experiences. But could also positive **emotional** experiences be a facilitator for personal growth? The idea that positive **emotions** are possible catalysts for growth has been explored by different theoretical frameworks in recent years, including the broaden-and-build theory (Fredrickson 2001; Fredrickson and Branigan 2005) and the “inspire-and-rewire” hypothesis (Keltner and Haidt 2003). Barbara Fredrickson’s broaden-and-build theory argues that **emotions** such as joy, interest, contentment, and love prompt individuals to *broaden* the range of thoughts and actions (e.g., play, explore, savor, and integrate) than is typical (Fredrickson and Branigan 2005) and help individuals *building* enduring

psychological, intellectual, physical, and social resources. For example, the positive **emotion** of joy creates the urge to play and get involved; however, playing also allows to create long-lasting resources, which are the skills acquired through the experiential learning it prompts. Some **emotions** bear a higher transformative potential than others: an example is **awe**, a complex, and little-understood emotion that lies “in the upper reaches of pleasure and on the boundary of fear” (Keltner and Haidt 2003, p. 297). According to Keltner and Haidt (2003) **awe** is characterized by two key appraisals: the perception of something vast and the subsequent need to accommodate the experience (Keltner and Haidt 2003). Vastness refers to any stimulus perceived as much larger than the self’s ordinary frame of reference: this can be represented by a natural event/phenomenon – such as witnessing a thunderstorm, the Grand Canyon, or a very tall mountain. However, vastness can also be conceptual, such as being presented with a complex idea, studying a beautiful equation or contemplating eternity (Keltner and Haidt 2003). The second appraisal of **awe** – need for accommodation – is defined by Keltner and Haidt as an “inability to assimilate an experience into current mental structures” (p. 304). It is a process by which individuals reconstruct their cognitive schema when a new experience cannot be adapted to their original cognitive structures. Crucially, according to Keltner and Haidt, accommodation can be either successful, leading to an enlightening experience (associated with an expansion of one’s frame of reference); or unsuccessful (when one fails to understand), leading to terrifying and upsetting feelings.

In recent years, several studies have begun to document the transformative psychological effects of experiencing **awe** (Chirico and Yaden 2018). Studies have found that **awe** can inspire a diminished sense of self (also known as “the small self” effect) (Keltner and Haidt 2003; Shiota et al. 2007; Campos et al. 2013; Piff et al. 2015) in which the self-concept becomes smaller and individuals view themselves less important and as part of a larger collective (Le et al. 2019). Empirical research has highlighted several beneficial

impacts of **awe**, including pro-social values (Piff et al. 2015), sense of social connection (Bai et al. 2017; Shiota et al. 2007), humility (Stellar et al. 2018), life satisfaction (Rudd et al. 2012), and meaning in life (Rivera et al. 2019). **Awe** was classed as a “self-transcendent experience,” defined as transient mental states characterized by decreased self-salience and increased feelings of connectedness to other people and one’s surroundings (Yaden et al. 2017). The self-transcendent constructs that fall into this category also include flow (Csikszentmihalyi 1990), mindfulness (Vago and Silbersweig 2012), mystical experiences, peak experiences (Maslow 1964), and positive **emotions** that entail a self-transcendent quality such as elevation, compassion, admiration, gratitude, love, and, as mentioned above, **awe**. According to Yaden et al. (2017), these mental states are experienced along a spectrum of intensity that ranges from the routine (e.g., losing yourself in music or a book), to the intense and potentially transformative (e.g., feeling connected to everything and everyone).

Roepke (2013) introduced a parallel concept to posttraumatic growth – the postecstatic growth model – that explores the positive psychological changes after **emotional** peak experiences like those described above. Roepke (2013) proposed that postecstatic growth occurs in specific areas, namely spirituality (having a closer connection to something bigger than oneself), meaning (having a clearer sense of the meaning of one’s life), social relationships (having deeper and closer relationships), and self-esteem (having more self-esteem). Considering that these perceived benefits seem significantly overlap with the positive psychological effects that have highly stressful events, Mangelsdorf and Eid (2015) suggested that posttraumatic growth and postecstatic growth may be similar processes, which can be facilitated by the same within-person factors following major life events independent of an event’s **emotional** valence: in other words, people who are more likely to experience posttraumatic growth are also more likely to experience postecstatic growth and vice versa. A recent meta-analysis (Mangelsdorf et al. 2019) covering 122 longitudinal studies found support for the existence of

actual posttraumatic and postecstatic growth, with positive trends for self-esteem, positive relationships, and mastery after both positive and negative events; furthermore, no evidence was found that negative life events have a stronger effect than positive ones, indicating that people tend to experience psychological gains over time independently from the valence of encountered life events.

Can Positive Transformative Experiences Be Elicited?

As self-transcendent **emotions** play a crucial role in personal growth, could it be possible identify ways for inviting, eliciting or facilitating such experiences? In human history, several cognitive techniques and artifacts have been developed to foster self-transcendent experiences. These include, for example, meditation, hypnosis, and other techniques for inducing altered states of consciousness (Tart 1972), including psychedelic drugs (Millière et al. 2018). In recent years, several scholars have started exploring the role of interactive technologies to help foster transformative experiences (Gaggioli 2016; Buie 2019; Kitson et al. 2019). Buie (Buie 2019) proposed to define a transcendent experience facilitated by technology as a “transcendent user experience (TUX).” For example, research has started exploring the potential of VR for inducing intense experiences of **awe** (Chirico et al. 2016). Chirico et al. (2018) describe results of a study, which tested the efficacy of virtual environments designed to elicit **awe** experiences, by enhancing perception of vastness and need for accommodation. Quesnel and Riecke (2018) tried to induce **awe** via a virtual environment that allows for the appraisal of the Earth’s landscapes, cityscapes, and a view of the planet from Earth’s orbit. To test participants’ **awe** intensity, the authors used a custom-made “goosecam” that is able to measure the frequency of goose bumps for each participant as well as subjectively reported feelings of **awe**. Results of the experiment showed that immersive **virtual reality** can elicit subjective experiences of awe and physiological goose bumps were observed in

several participants. Stepanova et al. (2019) provide a design framework to create **virtual reality** experiences of the “Overview Effect,” a profound cognitive shift reported by many space-travelers triggered by the sight of the earth from beyond its atmosphere (Yaden et al. 2016). According to Riva et al. (2016), **virtual reality** (VR) is a transformative **technology**, because it can modify our experience through the high level of personal efficacy and self-reflectiveness generated by sense of presence and emotional engagement. VR can be used to simulate “**possible worlds**” and “possible selves” and even simulating conditions that break the laws of nature, that is, by inducing the illusion of owning a different body. These unique features of VR, used alone or in combination with other brain-based technologies may create the conditions for inviting powerful transformative experiences (Gaggioli 2016; Riva et al. 2016).

Conclusions

Transformative change is one of the least understood mechanisms of psychological change. The systematic study of this phenomenon is only at start and common definitions and methods of analysis are lacking. However, the investigation of transformative experiences has a significant potential. From the scientific standpoint, the study of personal transformation could shed light on mechanism of discontinuous and nonlinear change, which has been a fruitful endeavor across the disciplines but not yet fully addressed in the psychological domain (Hayes et al. 2007). At the applied level, several authors have emphasized the clinical significance and potential healing effects of transformative experiences. The present review of relevant literature on transformative change allows identifying some potential avenues for interdisciplinary research on this elusive yet fascinating phenomenon. A first challenge concerns the development of a more comprehensive understanding of transformative change as a process, by focusing on its common antecedents, the experience of transformation, and its proximal and long-term outcomes. Although qualitative

accounts of these phases abound, quantitative research at multiple levels of analysis – that is, social, behavioral, and neuro-psychological – could also provide new insights on the phenomenon of personal transformation. For example, recent studies have begun to explore the neurobiological underpinnings of complex self-transcendent emotional experiences, such as **awe** (van Elk et al. 2019), **flow** (Cheron 2016), and mindfulness (Taylor et al. 2012), suggesting common mechanisms involved in these transient mental states at the brain level (Yaden et al. 2017).

At applied level, the study of transformative experiences could inspire the development of new clinical interventions and therapeutic techniques, at the same time improving our understanding of the mechanisms of change underlying them, that is, spiritual practices that have been used since ancient times. Along this line, it is important to consider the role that emerging technologies, such as **virtual and augmented reality**, could have in assisting a person going through a personal transformation (Gaggioli 2016; Riva et al. 2016). Indeed, an increasing number of studies show the potential of using these technologies for eliciting self-transcendent experiences, such as awe and **flow**, which are considered to hold a significant transformational potential. At the same time, ethical implications of transformative cognition should not be overlooked. Also, the integration of neuroscience methods and technological tools in the study of transformative experiences should be accompanied by careful considerations about the risks of embracing over-reductionistic stances, which could undermine the importance of adopting a holistic and multidisciplinary perspective in the study of this complex phenomenon (Schneider 2017).

In conclusion, the scientific study of transformative experience is attracting interest from a growing number of scholars in different disciplines. Although research in this area is still evolving, the understanding of fundamental mechanisms of personal transformation could carry wide-ranging implications. It is hoped that this analysis will encourage and stimulate further steps towards the establishment of transformative cognition as a mature scientific topic.

Uncertainty

Ronald A. Beghetto
Mary Lou Fulton Teachers College, Arizona State University, Tempe, AZ, USA

Abstract

Uncertainty is a gateway to the possible. Although the concept of uncertainty often connotes a negative or potentially hazardous state of being, scholars have long recognized that uncertainty also serves as a stimulus for new thought, beliefs, and actions. In this way, uncertainty can serve as an opening to the possible. The aim of this entry is to discuss how uncertainty has been conceptualized in the literature, including different types of uncertainty that people experience and how those experiences can propel us into the possible. Considerations for drawing connections among uncertainty, the possible, and related areas of inquiry are also discussed.

Definition and Overview

Uncertainty refers to a state of doubt. It connotes a lack of determinateness, sureness, stability, control, and predictability. Although uncertainty typically refers to one's own experience of doubt in the present moment, it also includes past- and future-oriented doubts about others, features of the environment, and the interrelationship among self, others, and context (Jordan and McDaniel 2014). It thereby refers to a present state of not knowing, a future oriented inability to confidently predict what will happen in the future and a potential lack of clarity of how to make sense of past events.

Given that uncertainty is associated with lack of clarity, control, and determinateness, it tends to be viewed as an unpleasant state that should be quickly resolved. In this conception, states of uncertainty serve as omens that signify risk and impending harm (Byrnes 2011; Reith 2004) and because people are risk adverse (Mumford et al. 2006), they attempt to avoid, manage, mitigate, and quickly resolve their encounters with uncertainty. Along these lines, there is a tradition of scholarship aimed at the “strategic management of uncertainty” (Collis 1992; Jauch and Kraft

1986). Such efforts are focused on planning for and controlling uncertainty in an effort to minimize potential hazards and maximize any potential benefits stemming from states of uncertainty. The notion that uncertainty can be managed, controlled, or even proactively eliminated has been traced back to what Reith (2004) has described as an “optimistic Enlightenment belief in the possibility of eliminating the uncertainties of the future through rational action in the present” (p. 384).

Not all scholars conceptualize uncertainty as a phenomenon that can be controlled or should be quickly resolved once experienced. Moreover, as will be discussed in the section that follows, there is a long line of scholars who recognize that although experiencing uncertainty is often uncomfortable and can sometimes result in negative outcomes, it can also be an animating force, which opens up new states of awareness and new possibilities for thought and action (Beghetto 2019a, c; Dewey 1910; Peirce 1958). It is this latter view of uncertainty that positions it as a gateway to the possible.

Uncertainty and the Possible

There are various ways we experience uncertainty and not all of our experiences with uncertainty motivate new possibilities. One way to think about our experiences with uncertainty is to recognize that it can be experienced at different levels of intensity. Indeed, given that daily life is always and already shot through with some level of uncertainty, we are not able to fully attend and respond to all of the uncertainties we face (Beghetto 2016; Dewey 1910). Some of the uncertainties we face are experienced at a lower level of intensity, what might be called *mundane uncertainties*, and often go by without much notice or response. Other uncertainties we face can be extremely intense or, what might be called *profound uncertainties*, which strike us as completely unknowable. Although profound uncertainties can be unsettling, we coexist with them even though there is little we can do to actively or ever resolve them. This leaves us with a wide variety of moderately intense

experiences with uncertainty, what might be called actionable uncertainty. Actionable uncertainty is a state of doubt that rises to a level of awareness whereby we find ourselves at an impasse *and* feel the need to explore and enact new possibilities. It is this latter experience of uncertainty that scholars have recognized as motivating new modes inquiry and new possibilities for thought and action (Bardt 2019; Beghetto 2019a; Dewey 1910; Glăveanu 2020; Peirce 1958).

The eighteenth-century French literary critic, Antoine Leonard Thomas (1773), for instance, underscored the primacy of doubt in thought and awareness. Thomas, in his commentary on Descartes, explained that although we dwell in a state of “universal doubt” and feel compelled to find a foothold when faced with doubt, doubt serves as basis for our thinking and existential awareness: *since I doubt, I think, since I think, I exist* (i.e., “Puisque je doute, je pense; puisque je pense, j’existe,” Thomas 1773, p. 25). In this construction, it is the experience of doubt that is primary to and opens up the possibilities for our thoughts (Dubito, Ergo Cogito) and actions (Dubito, ergo faciam, see Bardt 2019, p. 30).

Charles Sanders Peirce, the American Pragmatist and polymath, went further arguing that the only form of thinking that ever generates a new idea is that which occurs under a state of *genuine doubt*, not the paper doubts of philosophical speculation, but the upending doubt we feel when our typical forms of reason (e.g., induction and deduction) fail us. As Peirce has described it, new thought has its genesis in “some surprising phenomenon, some experience which either disappoints an expectation, or breaks in upon some habit or expectation” (Peirce 1958, n.p.). John Dewey (1910) similarly noted, that it is the “state of perplexity, hesitation, and doubt” (Dewey 1910, p. 9) that serves as the antecedent for new thoughts and actions. New ideas and behaviors become necessary under states of genuine uncertainty because our former ways of thought and action no longer serve us.

Actionable uncertainty viewed from this perspective represents a fundamental and continuous aspect of the human experience (Glăveanu 2020).

Indeed, although uncertainty may be anticipated and minimized through planning and imposed structures and routines, it can never be fully eliminated. This is because lived situations are dynamic and thereby always and already shot through with some level of uncertainty and risk (Beghetto 2019b; Breakwell 2014; Byrnes 2011). Rather than conceptualize uncertainty and the risks associated with it as an impending hazard, which is outside of our construction of reality (Reith 2004), scholars who view uncertainty as a signifier of the possible recognize that it can have both potential benefits and potential drawbacks. Moreover, they also recognize that attempting to avoid or rapidly resolve uncertainty can actually be more problematic than engaging with uncertainty and taking time to explore new possibilities (Beghetto 2019b; Byrnes 2011).

Encounters with actionable uncertainty thereby serve as a signifier that new thought and action is needed to arrive at a reasonable, albeit temporary, state of resolution. Instead of attempting to avoid or quickly eliminate uncertainty, we can learn to invite, engage, and sustain it by considering and enacting new possibilities. Indeed, as Dewey (1910) has explained, “acquiring the attitude of suspended conclusion” allows us to “maintain the state of doubt,” protract our inquiries (Dewey 1910, p. 13), and, in turn, realize new possibilities (Dewey 1910). Figure 1 illustrates this cycle of actionable uncertainty.

As illustrated in Fig. 1, encounters with actionable uncertainty serve as a gateway to the

possible, because they disrupt our expectations. These encounters often occur when we attempt to enact preconceived plans and designs. People who work with physical materials, for instance, quickly learn that no matter how clearly conceived a design they have in mind, once they attempt to enact their designs, the materials often “speak back” and resist their expectations. As Bardt (2019) has explained,

When we manipulate actual material, wood for instance, it continually surprises and overturns the mental ‘model’ of wood. (p. 28)

When a material doesn’t fit our mind’s assumptions – and it never does when we engage it – feelings such as doubt and belief emerge to be important ways to navigate the gulf between the mind’s stable concepts of material and material’s mutability. (p. 31)

The “gulf” that Bardt (2019) describes can be thought of as an opening or gateway for the possible. It is the liminal space we find ourselves in when the expected meets the unexpected (Aoki 2004; Beghetto 2017). It is in this in-between space where Dewey’s “attitude of suspended conclusion” becomes important – allowing us to explore and enact new possibilities rather than attempt to ignore, force-fit, or otherwise quickly resolve the doubt we encounter. Our encounters with actionable uncertainty are not limited to our engagement with physical materials, they also occur anytime we act in the world with overwrought expectations or plans.

Professional educators, for instance, often design highly planned and sequenced lessons. Indeed, educators learn to “plan away uncertainty” by detailing minute-to-minute activities and sometimes even rehearse scripted interactions with students in an effort to avoid the risk of encountering chaotic feelings of doubt or uncertainty when teaching (Beghetto 2017). Still, no matter how carefully planned and rehearsed a lesson, uncertainties still arise when the curriculum as planned meets the curriculum as lived (Aoki 2004).

Continuing with the example of teaching, there are various sources of rupture that can emerge when the planned lesson meets the lived lesson. These sources include (Beghetto 2017):

Uncertainty, Fig. 1 Actionable uncertainty

- *Social ruptures* (unexpected emotional, behavioral, ideational, and interactional responses of students, e.g., students engaging in side conversations, students getting upset, or taking the lesson in unexpected directions)
- *Internal ruptures* (unexpected responses of instructors, e.g., conflicting internal dialogues; recognizing a potentially new direction that the lesson can take; feeling disorganized, confused, frustrated, disconnected)
- *Material ruptures* (unexpected interactions, resistance, and problems with the planned use of tools, materials, and technologies, e.g., technology failing, learning materials affording unexpected uses)
- *Societal-situational ruptures* (unexpected situational, societal, and global factors that disrupt seemingly stable habits, routines, and expectations and result in states of actionable uncertainty, e.g., COVID-19 pandemic of 2020 causing school closures and resulting rapid and mass movement to online forms of teaching and learning)

In addition to these surprising encounters with uncertainty, it is also possible for encounters with actionable uncertainty to be designed into an experience to provoke possibility thinking and creative action (Beghetto 2019c). Intentionally designing or planning for uncertainty may at first blush seem oxymoronic. Indeed, how can uncertainty, which is a state of not knowing be planned or designed into an experience? Although it may be true, as Charles Sanders Peirce has argued, that genuine states of uncertainty, which engender situations of surprise, disruption, and unknowing, cannot be willed into being (Lane 2014); it is still possible to design situations wherein opportunities for encountering and working with uncertainty are purposefully induced.

An example of doing so, what has elsewhere been called *structured uncertainty* (Beghetto 2019c), involves designing experiences that blend predetermined elements with to-be-determined elements. The predetermined elements provide the *structure* to help guide the experience, such as providing criteria for success,

guidelines for engaging with the experience, and information on how assistance might be obtained during the experience. The to-be-determined elements represent the *uncertainty* of the experience because how those elements are engaged with and resolved is not known or determined in advance. Exploring the concept of structured uncertainty a bit further can help clarify how designed experiences can also serve as a gateway to the possible.

Let us take the example of a designed learning experience. Learning experiences can be thought of as including four core elements (Beghetto 2019b): the *what* (i.e., the task to be accomplished), the *how* (i.e., the procedures or approach for accomplishing the task); the *outcome* (i.e., the expected result of engaging in the task), and the *criteria* (i.e., the guidelines, rules, supports available, or other features that help determine a successful outcome). As has been discussed, most plans and designs endeavor to *eliminate* uncertainty by predetermining all the elements of an experience in advance (see Fig. 2, Panel A), whereas structured uncertainty blends predetermined elements with to-be-determined elements (see Fig. 2, Panel B).

Designed encounters with uncertainty vary in complexity with respect to how much uncertainty is introduced by the to-be-determined elements (Beghetto 2018). More specifically, as illustrated in Fig. 2 (Panel B), designed experiences can range from somewhat less complex experiences (e.g., a teacher teaches one way of completing a task and then requires students to come up with their own way of completing the task) to more complex experiences that include multiple to-be-determined elements (e.g., students are asked to identify their own task, their own way of completing it, their own products that demonstrate successful completion, and even assist with the development of criteria for success).

The more to-be-determined elements, the more uncertainty and, in turn, the more room for the possible. Even in designed experiences that include one to-be-determined element, the possible can still be animated in ways that enable all participants to explore and benefit from new

Uncertainty, Fig. 2 Variations in designing encounters with uncertainty

possibilities. Consider the example of a teacher who requires students to come up with their own way of solving a problem and the students collectively come up with and share with each other more than a dozen viable possibilities. The result of doing so can extend the possibilities beyond what any one individual in the group (including the teacher) could come up with on their own.

Finally, designing encounters with uncertainty also includes making sure that supports are available to people as they work with the to-be-determined elements (Beghetto 2018). Example supports include timely assistance (i.e., letting people know how they can receive as-needed assistance), dynamic challenges (i.e., increasing or reducing complexity by adding or removing uncertainty), and guidance (i.e., criteria, guidelines, and ground rules). These supports structure the experience and help to ensure that the uncertainty encountered remains actionable, rather than becoming over- or overwhelming.

Conclusion

Although uncertainty can be an uncomfortable aspect of our lived experiences, it can also prompt us to consider and enact new possibilities for thought and action. As has been discussed, not all encounters with uncertainty result in new

possibilities. There are, however, at least two instances when we can act on uncertainty. The first pertains to situations wherein our expectations run up against our lived experiences and our habitual ways of thinking and acting no longer serve us. In such cases, the doubt we encounter serves as a signifier that exploring and enacting new possibilities are necessary to work with and, at least temporarily, resolve the uncertainty we face.

The second instance where we can act on uncertainty is when we have designed experiences that require engagement with to-be-determined aspects of the experience. In such cases, we are presented with structured opportunities to engage with uncertainty in an effort to move toward a full array of new possibilities for ourselves, others, and our collective experiences in the world (Glăveanu 2018). Although we can experience some sense of resolution through the enactment of new possibilities, uncertainty always and already remains central to our experience and thereby can later necessitate further exploration and enactment of additional possibilities for the way we think, know, and act. This process occurs even in seemingly settled situations (e.g., scientific understanding, completed artistic works) as uncertainty can emerge from new ways of knowing and when “finished” works open to new interpretations (Anderson 1987).

Conceptualizing uncertainty as a gateway to the possible represents an important line of inquiry that offers an alternative perspective to conceptualizations that view uncertainty as something that should be avoided or immediately resolved once encountered. Indeed, viewing uncertainty as a gateway to new possibilities for thought and action can help us approach encounters with uncertainty with a willingness to suspend our desire to quickly conclude the experience and instead engage with this state of doubt in an effort to explore the new possibilities it affords (Beghetto 2016; Dewey 1910). This perspective is in line with descriptions of related experiences that help animate the possible, including the experience of wonder (Glăveanu 2020), states of awe (see Chirico, ► “Awe”), creative learning (see Beghetto, “Creative Learning and the Possible”), and risk taking (see Vacondio and Dickert, ► “Risk”). Future work building on a conceptualization of actionable uncertainty as a gateway to the possible can help advance theory and research aimed at exploring how unexpected and designed encounters with uncertainty open up new ways of thought and action for ourselves and others. Such efforts may also help us realize complementary perspectives in related and even seemingly incompatible work on uncertainty and the possible.

Unconscious in Philosophy

Alessandra Aloisi
University of Oxford, Oxford, UK

Abstract

The word “unconscious” (from the Late Latin *inconsci*, composed from the prefix *in-* plus the adjective *consci*) denotes, in a broader sense, that which is not conscious: more precisely, the set of those psychic or mental processes that escape consciousness or of which the subject is not aware. It can be used as both an adjective and a noun, but the second use appears only at the end of the nineteenth century, when the word “unconscious” begins to refer to a reality underlying consciousness or devoid of consciousness (see section Consciousness). As such, the realm of the unconscious will receive particular importance at the beginning of the twentieth century with the arrival of psychoanalysis, which will propose undertaking a systematic study of it.

The aim of this entry is to uncover some of the philosophical conceptions of the unconscious which preceded and were left aside by the emergence of the psychoanalytical model. In particular, we will focus on the idea of the unconscious that was first introduced by the German philosopher Gottfried Wilhelm Leibniz (1646–1716) (see section Leibniz). We will see how, within the context of Leibniz's philosophy, the problem of the unconscious appears not so much as part of an abstract theory of knowledge as part of a theory of perception (see section Aesthetics). After summarizing the context of the philosophical debate that led Leibniz to introduce his theory of “small perceptions,” this entry will show its possible implications for a general philosophy of the unconscious and its legacy in later thinkers.

Introduction

Speaking of the relationship between psychology and mental illness, Michel Foucault observed that we wrongly tend to think of psychology as that discipline which is supposed to explain madness and which contains, to a certain extent, the truth of madness. In reality, Foucault argues, it is madness that holds the truth of psychology, because it is madness, as that specific field of experience that we have begun to isolate and medicalize, starting from the mid-seventeenth century, which provides the conditions that make psychology possible and allows us to explain its emergence as a discipline during the nineteenth century (Foucault 1954, pp. 74–75). Something similar could be argued regarding the relationship between the unconscious and psychoanalysis. We tend to think of psychoanalysis as that specific discipline, form of knowledge, or practice that is intended to explain the unconscious and that would be able to reveal its truth or its functioning. However, it would be more accurate to reverse this relationship and see the unconscious as that specific field of investigation which, taking shape during the eighteenth and nineteenth centuries, allows us to explain the emergence of psychoanalysis.

Building on Ellenberger's pioneering work (Ellenberger 1970), scholars have started to regard Sigmund Freud not so much as the discoverer or inventor of the unconscious as the one who retrospectively polarized and systematized an already existing and multiform field of investigation (Rancière 2001; Aloisi and Camilletti 2019). If the term “unconscious” was introduced, in its substantive form, only over the course of the nineteenth century, the notion itself was not unknown before the term came into use. In fact, one may argue that this terminological innovation was indeed the result of a specific cultural process that had already been taking place, on a European scale, over the course of the eighteenth and

nineteenth centuries, at the intersection between philosophy, literature, and medicine, through a complex conceptual landscape which was not completely absorbed by Freudian synthesis and systematization. Viewed from this perspective, the notion of the “unconscious” reveals itself to be historically much more stratified, multifaceted, and composite than it appears when only considered within the narrative that culminates in psychoanalysis. As argued by Jean Starobinski, “Freud’s original contribution was not so much to have spoken of the unconscious but to have, so to speak, lifted the monopoly held on it by organic life and to have installed it within the psychic apparatus itself” (Starobinski 1990, p. 29). Freud, in other words, “dephysiologized” psychology and “desomatized” the causal system commonly accepted by his predecessors, assigning to the body a largely secondary role in the modern understanding of the unconscious, which ceased to have organic life as its main source (Vila 1998, p. 5).

The aim of this entry is to uncover some of the modern philosophical conceptions of the unconscious which preceded and were left aside by the emergence of the psychoanalytical model. Thanks to their heterogeneity in relation to the Freudian paradigm, not only can these conceptions provide tools for dialoguing with non-Western understandings of unconscious mental processes (Waldrom 2003), but also for meeting the challenge that cognitive science, by promoting an idea of “cognitive unconscious”, which reassesses the role of the body and the mechanism of adaptation over repression, presents to psychoanalysis today (Wilson 2002).

We will focus in particular on Leibniz’s theory of “small perceptions.” Developed in opposition to both Descartes and Locke, this theory promotes a specific idea of the unconscious which can be defined as a “differential unconscious” (Deleuze 1968, 1980). It is beyond the scope of this entry to show how, in other respects, the English philosopher John Locke could also be considered the initiator of a fragmentary conception of the self (“horizontal fragmentation”), which anticipates, albeit with substantial differences, a certain idea of the unconscious that will be endorsed by Freud (“vertical fragmentation”) (Goldstein 2005, pp. 3–5).

The Mind Always Thinks

The German philosopher Gottfried Wilhelm Leibniz (1646–1716) can be regarded as one of the first to have developed a theory of the unconscious within a broader philosophical debate concerning the nature of the soul and its relationship with the faculty of thinking. This debate – which overlaps with a series of traditional philosophical problems, such as that of the relationship between mind (“thinking thing”) and body (“extended thing”) or the question of the souls of animals – was characterized by two opposing positions: On the one hand, Descartes (1596–1650), according to whom the mind always thinks, and, on the other hand, Locke (1632–1704), who contested this Cartesian principle. Descartes’ position is clearly explained in a letter of 9 January 1642 to Guillaume Gibeuf:

The reason why I am convinced that the soul always thinks is the same that makes me believe that the light always shines, though there are no eyes seeing it, that the heat is always hot, though nobody gets heated; likewise, the body or extended thing always has extension; and, more in general, that which constitutes the nature of a thing is always in it while it exists. Thus, when one says that the soul ceases to think, it would be easier for me to believe that it would cease to exist, than to envisage that it could be without thought (Descartes 1996, v. 3, pp. 478–479).

If thought is the very essence of the soul or thinking thing, just as extension is the very essence of the body or extended thing, it follows that the soul, in order to exist, must always think. Our mind always thinks, even when its thoughts leave no trace in our memory (according to Descartes, this is indeed what happens almost every night when we dream, or during the day, when we have many thoughts that we do not remember). Likewise, light always shines, even when there are no eyes to perceive it, and the heat is no less hot from not heating anyone. The soul can therefore be without a certain thought, but never without thinking.

In 1670, Locke will question this principle according to which the mind always thinks.

According to Locke, this Cartesian assertion is radically contradicted by a simple piece of

evidence: “Most men pass a great part of their sleep without dreaming” (Locke 1975, book 2, ch. 1, sec. 15). Isn’t this enough to show that the mind can exist without thinking? Saying, as Descartes does, that even in the soundest sleep, the mind thinks but memory retains no trace of its thoughts is a nonsense in Locke’s view: “I would be glad to learn from these men who so confidently pronounce that the human soul [...] always thinks, how they come to know it [...], when they themselves do not perceive it” (Locke 1975, book 2, ch. 1, sec. 18). Assuming a philosophical perspective which recalls the objection that Aristotle himself had already addressed to the followers of the Megarian school, who were accused of confusing “actuality” and “potentiality” (Aristotle, *Metaphysics* 1046b 30), Locke will reply to Descartes that thought is not so much the essence of the soul as its faculty and that, as such, it may not be always actualized. Thinking, Locke argues, is “the proper action of the soul; yet it is not necessary to suppose, that it should be always thinking, always in action.” Thought is not to the soul what extension is to the body. The equivalent of thought is rather movement: It is no more necessary “for the soul always to think, than for the body always to move,” since “the perception of ideas” is to the soul “what motion is to the body, not its essence, but one of its operations” (Locke 1975, book 2, ch. 1, sec. 9).

If, leaving aside the philosophical jargon, we look at this debate from our own contemporary perspective, Descartes’ principle does not seem to pose as many problems to us as it does to Locke. Since we acknowledge without difficulty the idea that thought can be unconscious, we can also allow the possibility that the mind always thinks. However, to fully grasp the reasons for Locke’s resistance as well as the revolutionary nature of the solution proposed by Leibniz, it is necessary to point out that a central presupposition of these early-modern discussions around the nature of the soul and the faculty of thought is that “thinking and consciousness are strictly correlative: that thought, in other words, cannot occur without the thinker’s being simultaneously aware of it” (Heller-Roazen 2007, pp. 186–187). Of every thought, at the very moment in which we have it,

the mind is necessarily conscious, even when that same thought, once passed, leaves no trace in our memory. This fundamental principle of the Cartesian school was also accepted by its opponents, such as Locke, and allows us to understand how his criticisms actually pointed to an impasse in modern thought – an impasse that will be resolved by Leibniz.

Leibniz’s Theory of Small Perceptions

Leibniz’s idea of the unconscious takes shape within this polemic and presents itself as an original solution, because it implies a complete redistribution of the problems’ plan. Thanks to his “theory of small perceptions,” Leibniz can reassess on a new basis the Cartesian principle according to which the mind always thinks, while also questioning, at the same time, the implicit assumption, shared by both Descartes and Locke, according to which thinking coincides with consciousness. One of the earliest formulations of Leibniz’s criticism of Locke (later developed in the *New Essays on Human Understanding*, completed around 1709) is expressed in a letter to Thomas Burnett written in 1698. In this letter, Leibniz confesses to his correspondent that he shares “the sentiment of those who believe that the soul always thinks” and intends to demonstrate this assumption by using the same example of sleep. Even though he recognizes, with Locke, that there may be cases of dreamless sleep, Leibniz nevertheless observes that this does not prove that there has been a cessation of all movement in the soul. Even in these cases, Leibniz maintains, the soul does not cease to be affected by minute or “small perceptions,” which are not noticeable enough to be remembered. Even though they are too weak to be noticed, they are always retained, as are infinite other small perceptions that we have continually during the day. Leibniz then provides a range of evidence in this regard: Those who have slept in a cold place often notice, when they wake up, that they had a “confused and weak sensation” of cold while asleep. Likewise, Leibniz continues, “I know a person who wakes up whenever a lamp

that he keeps lit in his room at night goes out.” This makes it clear that “if one did not always have perceptions, one could never be awoken from sleep” (Leibniz 1978, v. 5, pp. 23–24).

Leibniz’s theory of small perceptions clearly represents, in other respects, a way to radically contest the Cartesian theory of the soul. According to Leibniz, the main fault of the Cartesians consisted in not being able to distinguish between “perception” and that which Leibniz himself calls, by coining a new term that will have a long philosophical and psychological afterlife, “apperception” (from the French verb *appercevoir*) (see section Apperception). As Leibniz explains in the *Monadology* and in the *Principles of Nature and of Grace Founded in Reason*, unlike perception, which is unconscious, apperception is the perception of perceiving, the perception accompanied by awareness (see Leibniz 1978, v. 6, p. 610). If the Cartesians do not make this distinction, it is because they count as nothing those perceptions of which one is not aware; this is the reason why they wrongly denied the existence of animals’ souls. However, what is interesting for our investigation here is that, used to defend.

The Cartesian principle according to which the mind always thinks, the theory of small perceptions entails a significant twist in this rationalist thesis, which is bent in the direction of the unconscious: Leibniz’s “insistence on the incessant activity of the mind quickly reveals itself to be, in truth, a vindication of an uninterrupted ‘thinking’ carried out beyond – or, rather, beneath – all the conscious acts of a clearly cogitating mind” (Heller-Roazen 2007, p. 185).

In doing so, Leibniz questions for the first time the idea according to which thinking and consciousness are strictly correlative, and that thought cannot occur without the thinker’s being simultaneously aware of it. If Leibniz introduced the term “apperception,” it was not so much to indicate the existence in the soul of such a thing as “consciousness” as “to clear a region within the mind for that which is not apperception and which accompanies it at every point: that state of mere ‘perception’ in which there is no awareness” (Heller-Roazen 2007,

pp. 204–205) – in other words, for that which will be called “unconscious.”

To sum up, while according to the perspective of early-modern thinkers such as Descartes and Locke, the idea of an “unconscious thought” is intrinsically oxymoronic, the theory of small perceptions allows Leibniz to show how, at every moment, there is an infinity of perceptions or modifications in the soul of which we are not aware, and which, nevertheless, take part in our conscious perception. The most famous example is that of the sea, described in the Preface to the *New Essays on Human Understanding*:

To hear this noise, as we do, we must hear the parts that compose this whole – that is to say, the sound of each wave, although each of these little noises is known only in the confused blend of all the others together, and it would not be noticed if the wave that produces it were alone. Indeed, we have to be affected a little by the movement of this wave and have some perception of each of these noises, however small they are; otherwise we would not have that of a hundred thousand waves, since a hundred thousand nothings could never produce a thing (Leibniz 1978 v. 5, p. 47).

In our conscious perception there is an indistinct background that is composed by an infinity of small perceptions (later philosophers, such as Maine de Biran, will prefer to speak of “affections”). Our mind’s incessant movement reflects the incessant movement of the universe as well as of our body (such as the circulation of the blood and all the movements that are internal to the viscera), even though all those movements in the soul remain imperceptible as such, in a single continuum of perpetual perceptions that ties all the affections together.

The Differential Unconscious

The metaphysical and theoretical implications of this theory are extremely fascinating from the viewpoint of a philosophy of the unconscious. This is the case first because it entails that, by means of its small perceptions, unaccompanied by reflection or awareness, every soul is a “monad” – that is, “an image of the Universe” that is perceived in its totality, according to

different degrees of obscurity, confusion, clarity, and distinction. In other words, every soul or monad is a “living mirror representing the Universe according to its point of view” and “with respect to its own body,” which determines its finite zone of clarity in the world (Leibniz 1978, v. 4, p. 562). This move has pivotal implications, in many ways analogous to those produced by psychoanalysis, to the extent that, by showing how mental activity and consciousness are not identical, it produces a significant reduction in the scope of conscious life and an extension of mental life and the unconscious. However, while psychoanalysis will accomplish this enlargement by going toward the most hidden depths of the subject, the extension of the mental dimension carried out by Leibniz does not go so much inward as outward, since the universe itself is included, more or less obscurely, in the perceptual ray of the monad.

Second, another pivotal aspect of Leibniz’s theory of the unconscious lies in the fact that it introduced a “differential” conception of the unconscious in its relation to consciousness. Between the small perceptions, of which we are not aware, and the apperceptions of which we are aware, there lies an *infinite difference of degree*, and each conscious perception is complex and composed of an endless number of successive perceptions, many of which remain unconscious. Every conscious perception represents a threshold and the minute perceptions correspond to its continuous and omnipresent background noise, which we always perceive even though we are not consciously aware of it. This theory – which will find its successors in authors such as Maine de Biran, Marcel Proust, and Gilles Deleuze, among others (see Kerslake 2007, Smith 2010, Milz 2020, Piazza & Vincenti 2022) – involves another essential difference with respect to the conception of the unconscious later developed by Freud, who finds his predecessors in a different philosophical tradition represented by Kant, Hegel, and Schopenhauer:

Indeed, Leibniz can be said to have developed one of the first theories of the unconscious, a theory which is very different from the one developed by Freud. The difference is that Freud conceived of the unconscious in a *conflictual* or *oppositional*

relationship to consciousness, and not a *differential* relationship to consciousness. In this sense, Freud was dependent on Kant, Hegel, and their successors, who explicitly oriented the unconscious in the direction of a conflict of will, and no longer a differential of perception (Smith 2012, p. 142).

In the Leibnizian theory of the “differential unconscious,” the unconscious therefore refers to that which escapes consciousness and remains unknown to it, not necessarily that which resists and opposes it. In every conscious perception there is necessarily a part that remains unconscious, not fully perceived.

Conclusion

The problems of the unconscious can thus be linked to the question of the possible or, more precisely, of the virtual (for the difference between “possible” and “virtual” see Deleuze 1966, ch. 5). In the Freudian view, the unconscious, finding itself in a relationship of conflict and opposition with the conscience, acts as that which attracts representations and snatches them from the conscience. On the contrary, in the idea of the differential unconscious promoted by Leibniz, small or unconscious perceptions are conceived of as “virtuals” that, without lacking any reality, can be actualized or not – that is to say, can become conscious or not, on the basis of shifting relationships of “compossibility” with a myriad of other perceptions that are related to our body.

Abstract

The concept of the unconscious in psychology (or unconscious mind) summarizes the complexity of the dynamics that characterize most of human's mental functioning. Since the paradigmatic revolution of the late nineteenth century, questions such as how the unconscious world is structured, how it influences cognition, emotion, motivation, and behaviors have pushed theoretical reflections and scientific research forward, always suggesting new reinterpretations of the concept itself. In particular, its impact on psychotherapy fostered the creation of different models and conceptualizations for treatment about the dynamics of the therapeutic relationship and the individual's mental functioning. Focusing on the realm of the unconscious mind inevitably opens the gates to the possible, encouraging the formulation of new vocabularies and taxonomies. This contribution offers a definition and a historical framework for the idea of the unconscious in the field of psychology. Then, from a brief review of the leading scientific research questions related to this concept, it reflects on the implications for clinical work and its associations with the possible in the therapeutic relationship. Insight and “aha” moments,

creativity, nonlinear dynamics, and approaches that combine the advancements of neuroscience and psychoanalytical contributions are just some of the theoretical and applicative branches that boldly ventured to “think the unthinkable.”

The idea of the unconscious (or unconscious mind) encompasses all the aspects of the way the mind works that the individual cannot grasp on a conscious level, thus reflects on them. Indeed, unconscious processes significantly influence motivation, memory, emotions, and in general everyone’s sense of self and identity (see chapter ► [“Consciousness”](#)). Although the term unconscious is relatively modern due to the contribution of philosophers such as Leibniz (1765) and Schelling (1800), the idea of the existence of elusive aspects of reality, which go beyond conscious reflection, is far from unknown in the history of art, religion, music, and of course philosophy. Indeed, the end of the nineteenth century represented an ideal cradle for the development of a more structured reflection on the unthinkable processes of the mind. The advent of non-Euclidean geometries, Schoenberg’s atonal experimentations, expressionism in figurative art and poetry are just some of the examples of an era in which new models do not merely substitute old ones. In fact, from the cracks that weakened previous paradigms once used to understand reality, it was possible to conceive new and extraordinary worlds in science, literature, and the arts. It is not surprising that on these bases, the then still young discipline of psychology began to try to find suitable answers to the questions revolving around the activity of the unconscious mind and how it influences cognition, emotion, motivation, and behaviors (Ellenberger 1970; Kandel 2012).

Starting from the Freudian contribution (see chapter ► [“The Possible in the Life and Works of Sigmund Freud”](#)), this entry will define the

concept of the unconscious in psychology and its historical roots. Moreover, it will provide a brief overview of research contributions on this topic, focusing on its impact on different dimensions of the mind (i.e., cognition, emotion, motivation, and behavior) as well as recent and challenging conceptualizations such as neuropsychanalysis. Finally, it will suggest a reflection on the most stimulating connections between the unconscious and the possible in psychotherapy, starting from the contributions on insight-like phenomena, creativity, and nonlinear dynamics in the therapeutic relationship (Lis et al. 2007).

Definition and Historical Roots of Unconscious in Psychology

The etymology of the word un- (“not”) conscious stems from the Latin word *consci*us (“knowing, aware”) from the verb *conscire* which assimilated *con* (“with”) and *scire* (“to know”).

The idea of “knowing” without actually “knowing” opens the doors of a paradox that is indeed only deceptive, de facto letting us conceive the possibility of an inner world of meanings (i.e., emotional, motivational) that moves within us without the consciousness being able to access it. The paradigmatic revolution, already mentioned above, represents the trigger that finally opened the gates to the exploration of the unconscious world.

Indeed, at the end of the nineteenth century, clinicians actively engaged in discovering the different mechanisms underlying the normal and pathological functioning of the mind (see chapter ► [“Psychopathology”](#)) but one decisive contribution was Sigmund Freud’s that, in his famous volume *Die Traumdeutung* (“The interpretation of dreams,” 1900) theorized the existence of the unconscious, a part of the human mind in which our deepest desires, needs, and feelings are hidden.

Freud used the apt metaphor of an iceberg to describe the three parts that define the structure of the human mind: only a small part of the iceberg floats out of the water representing the conscious mind, as a layer immediately under the surface is

the preconscious mind, while the greater portion of ice, hidden from the conscious world above, represents the unconscious mind. As the conscious mind contains all the elements of which we are aware, which we can have a mental representation of, the preconscious mind retains all that is out of our consciousness but can quickly become conscious given a small effort of attention or remembrance.

However, this model's real innovative contribution was the idea of the unconscious mind, where all of the most important desires and fantasies flourish, free from most of the constraints that regulate the functioning of the other two parts of the mind. Indeed, the unconscious objects and often conflicting forces are trapped from the possibility of introspection, held prisoners by our inner censorship because of their unacceptability: thus, all these unconscious elements create mental energy that needs to be freed. In the same essay, Freud explains how, during the nightdream, the unconscious material is represented through different images to the individual's awareness though still transfigured by the influence of different mechanisms of the psyche (see chapter ► "Dreams").

Moreover, in 1901 Freud publishes "*Zur Psychopathologie des Alltagslebens*" ("The psychopathology of everyday life") in which he introduced what he calls slips as representations of the conflicts that happen in the unconscious mind. In this essay, Freud discusses the idea that there are specific deviations in everyday behaviors, such as forgetting things, or saying one word instead of one another, or other random actions are clear signals of our inner turmoil. We usually do not notice these kinds of mistakes, but thanks to the psychoanalytical method, this material can be analyzed to understand our most profound nature better.

Later on, in "*Das Ich und Das Es*" ("The Ego and the Id"; 1923) Freud suggested a second model for the structure of the mind in which the unconscious still played a fundamental role in the definition of inner conflicts and psychopathology. All in all, the Freudian model signified an unprecedented stimulus in exploring the complexity underlying human behavioral phenotypes.

Another relevant contribution to the comprehension of the unconscious was Jung's conceptualization of the collective unconscious (1912). Although Jung distanced himself from the International Psychoanalytical Association's dogmatic theories, his theorization of the collective unconscious is still considered one of the most critical contributions in psychoanalysis.

Jung brought up the idea of the collective unconscious by analyzing some delusional processes in schizophrenic patients, suggesting the existence of an immutable common representative knowledge heritage that transcends time and space and is acquired indistinctly by all humankind. Jung identified two fundamental elements to describe the collective unconscious: instincts, intended as all the natural reactions that did not come from learning, and archetypes, meaning representational contents that belong to all humankind. However, Jung was not completely satisfied with his theorization as, in "*Wandlungen und Symbole der Libido*" ("Psychology of the Unconscious"; 1912), he stated that there is no hereditability of the specific representations, but there is hereditability of the possibility of representations.

Another fundamental intuition was Bion's idea of the inaccessible unconscious a fourth category of the psyche added to the three of Freud's first model, which stores all the mnestic traces of intrauterine life, including primitive traumatic experiences of frustration that cannot be mentally represented. Bion (1962) introduced the concept of Beta elements, that is, raw emotions representing primitive experiences that we cannot think about or even transform in dream-like materials. Nor the conscious or the unconscious mind can store these elements: it is the Alpha function that transforms these basic feelings in elementary representations of mental contents that we can think of (Alpha elements).

In opposition to the psychoanalytical standpoint that was very popular in psychology during the Fifties of the twentieth century, cognitive approaches to psychology began to gather empirical evidence on mental processes and their

functioning. An essential limitation of the Freudian unconscious concept was the impossibility of observing, manipulating, and measuring it in its components through the scientific method. Things started to change thanks to a seminal contribution from Nisbett and Wilson (1977) that explored from a cognitive standpoint to what extent we can be aware of the reasons behind human behaviors. At a time when higher functions of the mind, such as behavior, were processes that could only be explored by consciousness, the idea of being able to “telling more than we know” opened a crack in the cognitive paradigm, allowing the science of the mind to develop its exploration of the dynamics and features of the unconscious mind.

Hence, a decade later, Kihlstrom (1987) theorized and empirically analyzed the so-called cognitive unconscious. In his innovative work, he demonstrated how cognitive functions such as memory and perception could occur outside the individual’s consciousness. Indeed, he demonstrated that many mental processes that pertain to a more procedural knowledge happen outside of the realm of awareness and are activated without any introspection. One of the most common examples in psychology about procedural memory is the ability to ride a bike: once learned, we cannot think about it and divide it in sequences of actions because it now belongs to the cognitive unconscious.

This brief historical excursus lays the foundations for understanding how research has tried to explore the unconscious processes of the mind. Indeed, the introduction of the cognitive unconscious allowed to methodically approach the exploration of the more deeply submerged part of the Freudian iceberg, highlighting some pivotal questions to which the research of the following decades will try to give an answer: what cognitive processes must we study to understand the unconscious dynamics of the mind? How much of our conscious life is influenced by unconscious processes? What are the implications for clinical practice and psychotherapy? These are just some of the burning questions that have driven scientific research since the second half of the twentieth century.

Research on Unconscious in Psychology

Freud, like Elvis, has been dead for a number of years but continues to be cited with some regularity. Westen (1998)

As Drew Westen wrote in 1998, reflecting on the scientific legacy of psychoanalysis and acknowledging and focusing on the unconscious lead to three radical shifts: first, the cognitive revolution that put at the center of scientific reflection the study of mental processes, even unconscious ones; second, the developments of psychoanalytical thinking to explain how our inner world develops (adaptively or not) according to socio-cultural contexts and experiences; and last but not least, the epistemological shift that has allowed us to explore the processes of the mind in the light of emotions and motivation, two central components of the psychoanalytical contribution.

This brief overview of the literature summarizes some of the main directions in which research explored the mind’s implicit dynamics.

Starting from Kihlstrom’s conceptualization of the cognitive unconscious, scientific research, despite the disagreements with the psychoanalytical theories, recognized that most mental processes are unconscious. In particular, cognitive science has long and thoroughly explored aspects related to the functioning of implicit memory, that is, that part of memory that can be observed in behavior but cannot be recalled consciously. One type of memory, already mentioned above, is procedural memory that stores all the “instructional manuals” that allow us to perform the most diverse actions and tasks without thinking about them. Another example of unconscious (implicit) memory is the one that emerges from priming experiments where previous exposure to a stimulus (prime) that is associated with meaning allows us to acquire new information more quickly (Bargh 2006). An exciting research area on the cognitive unconscious explores the processes of learning and re-elaboration of information that has its basis in the most recent theories on neural networks and implies the presence of unconscious processes in the learning of new information as in problem-solving and decision making. All in all,

numerous contributions from neuropsychology research involving patients with specific brain damage and research on priming from social psychology exhibited evidence for the human ability to perform complex behaviors unconsciously. This underlines how the scientific community readily accepted the existence of unconscious cognitive processes (Bargh and Morsella 2008).

However, a few years will pass from Kihlstrom's initial contribution for research to explore the other two crucial dimensions that Freud theorized as primary forces of unconscious functioning: emotion and motivation. Kihlstrom et al. (2000) suggested the existence of two processes behind the observable effects of unconscious emotions. First, they theorized the existence of "unconsciously generated emotions" that encompass all cases in which the individual can experience and recognize his or her emotional responses, but cannot trace back their unconscious causes (e.g., memories, thoughts). A simple example of unconsciously generated affects in clinical psychology is in individuals that suffer from anxiety: A specific characteristic of these manifestations is the full awareness of the emotion arising (e.g., fear of dying) without the possibility of a direct connection with the mental states that caused it. Second, Kihlstrom and colleagues defined the case of "implicit emotions" where the subject is not aware of his emotional states or otherwise able to recognize them, even though it is possible to detect the emotional activation in the brain through specific techniques. Indeed, since the study of consciousness (and non-consciousness) is not possible in animal models, the advancement of brain process investigation techniques has been a driving factor in research on emotions and their regulation. Scherer (2005) defines them as "the bulk of the iceberg," underlining how most of our emotional functioning interchanges on an unconscious dimension. Numerous studies on the contribution of brain areas such as the amygdala have demonstrated the subsistence of these processes (Smith and Lane 2015).

Another aspect, perhaps the most radical of the Freudian theory, was putting motivation within the unconscious processes: This implied the

fundamental assumption that "the why" of our actions, thoughts, and behaviors pertains to an unthinkable dimension. Thus, the root of who we are, our self and identity, stems from the unconscious. The debate between psychoanalytical theories and cognitive sciences witnessed the latter rejecting this possibility for a long time. On the other hand, phenomena such as defense mechanisms are clinical examples of how individuals protect themselves from unconscious desires and motivations.

In 1989, McClelland suggested the distinction of implicit and explicit motives, highlighting the difference between research on motivation through indirect methodologies (e.g., projective measures) instead of self-reports: the former has shown a higher value of predicting behavioral outcomes. It makes sense that what is measured associatively (i.e., implicitly) instead of self-reported is less influenced by other variables (i.e., individuals might be unwilling to show their real motives or may even be unaware of them). Moreover, research on attitudes has made valuable contributions by showing how (unconscious) prejudice guides social behavior. Betsch et al. (2001) explored a theory that explains how our evaluations are implicitly formed, preserved as mnemonic traces, and used to judge specific targets. The underlying hypothesis is that our implicit value attributions (value accounts) influence the way of expressing an evaluation more than the traces of past experiences, especially under pressure. Recently, Kihlstrom (2019) reviewed the evidence that motivation, similarly to emotions, works on an unconscious level in different ways. First, it can be elicited unconsciously by external stimuli. Second, it can be elicited unconsciously by external stimuli that are also unconscious. Finally, the individual can be "aware of not being aware" of his/her motivations.

It will take about a century for psychoanalysis and the advancements of neural science to finally cross paths. With the advent of neuropsychanalysis (a term coined only in 1999), research finally manages to resolve the epistemological dualism between psychodynamic and neuroscientific traditions. In this sense, the search for the

neural bases of the unconscious represents a fundamental step.

Mark Solms (2017), a neurologist but also a psychoanalyst, represents one of the exponents of this new paradigm, providing data on the location of the unconscious within the functions of the brain. A central aspect of the contribution of neuropsychanalysis is the centrality of emotions in the organization of psychic life. While the cognitive approach to unconscious was unbalanced on aspects related to information processing, the shift to emotional aspects represents a radical change. Experience is processed and elaborated through a first instantaneous, subcortical, phylogenetically embedded response that immediately tells us (without us being able to perceive it) if a stimulus is threatening our survival. Subsequently, the stimulus is elaborated in a more sophisticated way on a cortical level, drawing on the mnemonic traces that are already present. In this way, neuropsychanalysis shows how most of our mental life takes place at an unconscious level, at the very basis of that iceberg that Freud had first imagined.

Research on the unconscious theorized as a set of implicit processes that encompasses cognition, emotion, and motivation has allowed substantiating the most important Freudian intuition. That is, most of mental life happens without us thinking about it, and the unconscious universe, which influences our choices and behaviors, is complex and fascinating. We will discuss some of the clinical implications of these considerations in the next section.

Unconscious and the Possible: Insight, Creativity, and Nonlinear Dynamics

In the dance we need to have a moment of waiting, not knowing what is coming next (the moment of *maybe*) for the dancing to be real. What we do next *is not known*, in a sense *does not exist* until the two partners construct it, each with his or her separate roles.

Bucci (2011)

Some of the initial questions of this contribution have already been answered thanks to the data

and considerations emerging from research and theories on the unconscious: a large part of the human mental activity takes place beyond consciousness, and different dimensions contribute to it (i.e., cognition, emotion, motivation). The question that still needs an answer (at least one among the possible ones) is what are the implications that scientific discoveries coming from cognitive sciences, neuroscience, and psychoanalysis have for clinical practice and, at large, for a framework of thinking on the human mind. Freud suggested some of them in his psychopathology of everyday life, as well as with the introduction of the dynamics related to transference (where the patient projects thoughts, feelings, and emotions from a past relationship onto the therapist), countertransference (where the therapist “resonates” of the patient’s inner world), and dream analysis.

Allan Schore, one of the pioneers of neuropsychanalysis, carried forward the concept of the implicit self, arguing that in addition to memory, thought, learning, and attention (all the processes highlighted by cognitive psychology), it is necessary to introduce the notions of implicit affect, implicit communication, and implicit self-regulation. As already anticipated in the previous section, the role of implicit emotion is one of the central aspects of the contribution of neuropsychanalysis: Adding communication and self-regulation to the equation fosters a thorough reflection on the impact of unconscious dynamics in psychotherapy. Indeed, the therapeutic relationship becomes a privileged place of observation of the “relational unconscious” as it is guided by the right hemisphere of the brain, working via associations and primary processes that we can also find in dreams and reveries (Schore 2011).

Indeed, it is in the therapeutic relationship that a fundamental manifestation of unconscious processes finds its place, the so-called “aha” moment in which new and unexpected elements come to light. As pointed out by Domash (2010), insight (which is “seeing/understanding from within”) frequently occurs in cases where stagnation is perceived, from the feeling that the therapeutic process is somehow facing an impasse. This is similar to a cognitive restructuring that includes

the emotional experience and marks a decisive point in the perception of the context and its meanings. Neuroimaging studies have shown that insight is a creative act that emerges from consciousness by bypassing logical reasoning (*ibidem*). Thus, the link between unconscious and creativity finds its possible manifestation in the psychotherapeutic relationship: the generative effort that allows the passage from one state of the mind to another unrelated requires an implicit intuition, embodied and embedded in experiential knowledge.

The understanding of creative processes in the therapeutic relationship, as well as in other contexts, unfolds through the subjective narration of the experience itself (the “aha” moment). As Nancy Andreasen explains:

The person is typically in some type of reverie or dissociative state when the mind wanders freely, and thoughts and images float around without censorship. During this fluid time, the brain is probably working feverishly, despite the subjective sense of reverie and relaxation. [...] As we think about this process using the terminology of mind and brain, then the primordial soup is the unconsciousness and process of making connections must arise from the efforts of the association cortex. (2011, p. 45)

Since the end of the twentieth century, the theory of psychotherapy has seen a significant revolution in the adoption of an interpersonal perspective. In this way, a significant gradient of complexity has been added, shifting the focus not only on the patient and the therapist’s internal dynamics but also on their interaction within the clinical relationship (Locati et al. 2017; Benzi et al. 2020). Thus, implicit processes that were previously a subjective dimension become shared implicit processes and, therefore, need new models to be explored. An intriguing perspective is offered by the theory of nonlinear dynamic systems that describe the processes of change, adopting a multifaceted perspective where every element considered is context-sensitive and varies upon different degrees while interacting with other elements. Borrowing the language of physics, Stolorow (2013) describes the process of change in psychotherapy within the intersubjective

relationship as nonlinear, unpredictable, and discontinuous and proposes a fascinating conceptualization of processes (even unconscious) in the therapeutic relationship.

Within the psychoanalytical framework, Bucci (2011) suggested an innovative model of psychopathology that focused on dissociation and stressed out the importance of the interpersonal relationship in psychotherapy, rooted in the advancements of both cognitive and affective neuroscience. This framework underlines the hypothesis that “in the treatment, the sub-symbolic communications potentially open new connections to the symbolic mode, which then feedback to deepen the subsymbolic explorations, and new, emergent shared schemas are constructed” (*ibidem*, p. 45). Overall, beyond the theoretical milieus, a crucial focus of the psychotherapeutic relationship is the possibility of bringing manifestations of the unconscious to the surface in order to integrate them into the patient’s experience (Craft 2014; Benzi et al. 2018).

This brief excursus reviews some of the main developments on the unconscious in psychology. Within different theoretical paradigms, the exploration of the “unthinkable” world has allowed us to advance in the mind’s knowledge, even the conscious one. Therefore, the great challenge for researchers, clinicians, and anyone who ventures into the understanding of the functioning of the unconscious mind is to be able to imagine a universe that runs with different rules, nonlinear and unpredictable, but above all, is to find the right tools to be able to describe it.

Studying the unconscious requires a creative effort in itself and the willingness to explore impossible routes, at least on paper.

Utopia

Gabriela Manley

University of St Andrews, St Andrews, UK

Abstract

In common vernacular, Utopia usually conjures up imaginations of an impossible place marked by its perfection and happiness. However, this represents but one of the many ways in which utopias can be understood. When studied closer, utopian studies scholars have found it hard to

reach a consensus on what a utopia is, and what it is for. Broadly speaking, we can find four different ways of understanding utopia: as a literary text; as a blueprint for society; as a critical reflection of the present; and as a simple pursuit for a better life. Crucially, all these categories speak to the possibility of a different way of life, be it elsewhere in space as with early utopian texts, or elsewhere in time as is most common in contemporary utopias. Utopias which exists elsewhere in time speak most directly to what is possible, as placing them in our own future serves to incite us to work toward them, making changes in the present that might approximate this possible future. This is the aim of most living utopian movements today – from #Occupy Wallstreet to new gene editing technology – which not only presents us with a vision for a possible utopia future, but also tells us how to get there, making the possible increasingly tangible.

Keywords

Utopia · Utopian · Future · Possible · Critical Utopias

Introduction

The origins of the concept of utopia are as hard to pin down as the meaning of the concept itself. The genre and the word were of course introduced by Thomas More in 1516, entering the common vernacular through his publication of *Utopia*. However, utopias as a concept are as old as political thought itself (Sargisson 2007), and although Plato's *Republic* is often considered the best-known early utopia, Sargent and Claeys (1999) open their *Utopia Reader* with a passage from Hesiod, dated back to eighth century B.C. In fact, More himself did not work on a *tabula rasa* to create his *Utopia*, but built on traditions of thought that can be traced back to ancient Greece and myths of the Golden Ages, making connections between the classics and Christian traditions to build a new imaginary world (Vieira 2010). More, therefore, provided us with a new word and new tools to explore a concept as old as politics; that of “the desire

for a better way of being” (Levitas 1990) – whatever this may be.

The word “utopia” is derived from the union of three Greek terms: *eu*, good; *ou*, non or not; and *topos*, place; creating an etymological pun that literally translates to “the good place that is no place.” By indicating a place which is not a place, it is creating a concept constituted by simultaneous affirmation and denial. This dissonance contained in the very name forms part of the core properties of utopia, which render utopia itself unachievable (it is, and yet it is not), and thus maintains it firmly fixed in the realm of the possible. It is this post-More iteration of utopia that concerns most scholars today, as it has encapsulated many attributes of modern thought (Vieira 2010). From global utopian movements such as #Occupy to modern debates on the future of gene modification and eugenics, imaginations of the possible future serve as critical reflections on the present (Moylan 1986).

The vague and paradoxical origin of utopia as “the good place that is no place” has allowed it to continuously acquire new meaning, serve new interests and morph into new concepts throughout the centuries. This diffuse nature – from politics, to literature, science, and art – has been at the basis of debate among researchers of Utopian Studies who have often found it difficult to reach a consensual definition.

Defining Utopia

Historically, utopia can be seen as broadly defined under four separate terms. First, it can simply be seen as the literary form that crystallizes the imaginations of utopia (such as More's *Utopia*, 1516). However, this definition is narrow to the extreme, excluding all nonnarrative texts and raising complicated categorical questions on what counts as a “utopian text.” Fredrick Jameson (2005:2) rightly points out that although there has often “been a need to distinguish between the Utopian form and the Utopian wish,” the life works of Ernst Bloch serve as a stark reminder of the impossibility of the task of separating the two, utopia being “a good deal more than the sum of its texts.”

Secondly, Utopia has been understood as the content of the imagined society. This is to say, what makes “the good place?” What is good and what is not? What would a perfect society look like? This approach to utopias has been the main focus of much anti-utopian scholarship as at its core it is making an association between utopianism and perfectionism and utopianism and fundamentalism, leading it to be routinely associated with authoritarian political regimes such as Hitler’s fascism and Stalin’s communism (Sargisson 2007). Both Karl Popper (1962) and Edmond Burke (1790) identified a certain totalitarianism at work under this definition of utopia rooted in the idea that no utopia is perfect for everyone, as utopia – under this definition – relies on the impossible requirements “that there are rational methods to determine once and for all what this ideal is and what the best means of its realization are” (Popper 1962: 161). Popper’s criticisms have been influential, with Leonard Shapiro (1972) and Jacob Talmon (1961) building on this idea of the utopian imagined society as a blueprint for the “perfect place” to construct a picture of utopia as the antithesis of liberalism. They are not the first to associate the idea of utopia with perfectionism. Early scholars such as Kaufmann (1879 quoted in Sargisson 2007: 12) popularized this relationship between perfectionism and utopia, describing it as a “happy island far away where perfect social relations prevail,” a definition that continues today in the common vernacular and dictionary definitions, becoming the most recognizable feature of utopia outside of utopian studies. Although many responses and criticisms have been levied at this approach of utopia as a blueprint for the perfect society (see Goodwin and Taylor 1982) many scholars of utopia today point to the *key* flaw in this approach lying in the very way utopia is being defined arguing that “the function of utopia is not its own realisation” (Sargisson 2007: 31). Referring back to the original meaning of the word (i.e., “a place that is no place”) they stress the idea of utopia as an inherently unachievable project, an end goal that never arrives, remaining by its own definition in the realm of the possible (Jameson 2005, Moylan and Baccolini 2007).

The third definition of utopia follows from these criticisms of utopia as a “blueprint” and takes on a functionalist approach, understanding utopia through its function as a tool to impact the reader, urging and encouraging change. This is the basis for what Moylan (1986) has termed *critical utopias*. Drawing from the works of Ernst Bloch and Fredric Jameson, Moylan argues that critical utopias are “explicit attempts to challenge and undermine hegemonic structures of political power in a common quest for emancipation while retaining and emphasizing the dangers inherent in totalizing visions” (Lancaster 2000: 111). In other words, the critical utopia functions to challenge traditional dualistic understandings of political possibilities by showing the ways in which revolutionary change can take place. A critical utopia aims to provoke change and action in the present by showing the possible otherwise. In this way, the function of utopia is indeed not “its own realisation,” nor is it a blueprint for an ideal society, but a means for critical reflection, change, and aspiration toward which we should always strive. Crucially, then, these utopias are not static, but ever developing as the horizon of what is possible changes (Jameson 2005; Moylan 2007; Sargisson 2007).

Although this approach has proven widely popular, Fatima Vieira (2010) (see also Levitas 2007) has argued that it limits what we may understand as “utopia” to the realm of the political, and proposes the fourth and final general definition of utopia as “a desire for a better life caused by a feeling of discontentment towards the society that one lives in” (Ibid. 6). Maintaining the definition of utopia so broad allows for the inclusion within the framework of utopia a vast range of texts informed by what Bloch (1986) considered to be the cornerstone of utopia: hope. Utopia here is then to be seen as a matter of attitude of aspirations to “a better life” inspired by the imagination of alternative possibilities. For Bloch (Ibid.), the impulse to achieve utopia is a subconscious ontological inevitability, as humankind cannot escape this constant longing for a better world. However, as Jameson (2005) points out, this leads us to a hermeneutic problem when we consider overtly self-conscious utopian projects and their relation to the subconscious ontological

structures Bloch is suggesting. Instead, Jameson (Ibid.) suggests an alternative way of reorganizing this “desire for a better life” into three separate categories of body, time, and collectivity.

It is these final two categories of utopia that are currently most widely explored among utopian scholars as they allow this vast and complex genre the greatest level of flexibility and critical reflexivity. Crucially, however, by adopting More’s paradoxical concept of the utopian “place that is no place” all four categories of utopia discussed fall under the realm of the possible, dealing with imaginations of a world as “other” that is related to our present state, either as an inspirational future (Sargisson 2007) or a critical warning (Moylan 1986). Broadly speaking, this utopian “other” occupies either a different place or different time and can represent positive or negative possibilities.

Utopias Elsewhere in Space

The “possible other” of utopia is originally found occupying a different *space* – rather than time – as the reader. More’s original *Utopia* describes Utopia as an island, which exists in the same time as More himself but finds itself isolated from the external world. The island is described as almost entirely free of external contact, with its precarious waters and strangely shaped land preventing outsider ships from finding it. It has existed in this isolation for centuries, and therefore its history and development are to be seen as separate from our (the reader’s) own. The island exists in our world, yet in a way it is not *of this world*. This topographical rupture created through isolation allows the utopia to break away from the socio-historical constraints of our “real world,” freeing up infinite possibilities for the creation of this new place where the author’s imagination can truly run wild and create “from scratch” another possible world. This is characteristic of the onset of utopian literature where we find static, a historical utopias most reminiscent of the first two definitions discussed above (Vieira 2010) (although there has indeed been heated debate on the correct reading of More’s *Utopia* (Davis 2010)).

Traditional Scottish folklore, for example, builds on this model of utopia with its tales of Brigadoon: a village that became enchanted centuries ago, becoming isolated and invisible to our world except for 1 day a year where it would become visible and accessible to outsiders. Much like *Utopia*, the town of Brigadoon is described as isolated, idyllic, and free of evil, remaining unaffected by time as the centuries pass.

These traditional Renaissance and early modern utopias were heavily influenced by contemporary quests of discovery and colonization, borrowing – sometimes directly – from current colonial conquests and new worlds (Pohl 2010), and would often justify the colonial process through these ideas of utopia by introducing “perfect systems” into new “primitive” societies. Francis Bacon’s *New Atlantis* (1627), Francis Godwin’s *A Discourse of A Voyage Thither* (1638) and Gabriel Plattes’ *A Description of the Famous Kingdome of Macaria* (1641) all follow similar patterns, displacing their utopias by placing them in faraway lands and undiscovered territories that bear a striking resemblance to current discoveries at the time, from the disastrous colonization of Guiana to the finding of Bermuda and the “New Worlds” of the Americas.

Early utopias set “elsewhere” in space rather than time often find themselves rejecting a temporal dimension at all, being imagined as a-historical by ignoring the past, and a-futural by eliminating the idea of progress and future from their horizon (there is no possible progress in a society which has achieved perfection). Presenting utopias in this way does invite the reader to take them as blueprints to follow or aspire to. Problematically, it critiques the current society and presents a utopian alternative without suggesting pathways to get there (Vieira 2010), leaving itself open to anti-utopian criticisms of the “ends justifying the means” (Popper 1962) – Nazi Germany comes to mind here. Further, these early utopias tended to impose archaic ideas of Paradise onto the real world, evoking imaginaries of the lost Golden Ages as a basis for their possible Utopias (Pohl 2010), offering us a very narrow version of what “a good place” ought to look like and raising the problematic moral questions posed

by anti-utopian scholars, in particular when taking into account the colonial influence on these texts.

Utopias Elsewhere in Time

In the eighteenth century utopias shifted from existing exclusively elsewhere in space, to existing elsewhere in time. Heavily influenced by the enlightenment discourses of progress, reason, sociability, and reform, utopian writers shifted their focus from “elsewhere,” introducing the first utopias to be set in the future (also known as *euchronias* or “the good place in the future”). Utopias which exists elsewhere in time are far from a-historical, embracing history as a process of infinite improvement in which we can imagine utopia as the possible end product of modern progress. By projecting utopia into the possible future, the discourse enunciates a logic of causalities that presupposes certain actions (mainly those of political nature) might spur on the changes needed to achieve the imagined utopia (Vieira 2010). These utopias are therefore dynamic and a degree more flexible than utopias elsewhere in space.

Placing utopias in the future allows them to hold a distinct political dimension. They encourage us to work toward them, approximating this possible “other” by placing it in the imagination of our own space and time. Marx and Engels’s communist project can be seen as one such utopia (Moylan and Baccolini 2007) where historical consequences coupled with political progress may lead us to a changed new world (although Marx and Engels would balk at the idea of their project being described in this way, having considered the idea of utopia to be negative and detrimental).

Some utopian socialists went further than simply imaging a future utopia, creating small idyllic societies that demonstrated that utopia was indeed possible. Such were the communities of New Lanark in Scotland and New Harmony in Indiana that Robert Owen built as the basis for the creation of what he called “a new moral world.” In these communities, people lived with unprecedented social and worker’s rights, children attended free

and mandatory education, workers experiencing reduced hours and free access to healthcare among many other “idyllic” social reforms while still driving a thriving economy. Owen, in this way, aimed to prove that a socialist utopia in the future *was* possible though political reform. Utopias set in the future, then, present utopia as something not only theoretically possible, but accomplishable through progress, ascribing this possible “other” a much more concrete dimension. In these utopias, the present should therefore be understood in terms of its fulfillment of the future.

This is what forms the basis for Moylan’s “critical utopias” (1986). What utopia becomes is not a static, isolated blueprint of “a perfect place” but a possible future attainable through real change in the present. These utopias are “no longer the exhibit of an achieved Utopian construct, but rather the story of its production and of the very process of construction as such” (Jameson 2005: 217). Placing the utopias in the possible future of our own world allows them to perform the function of social critique in the present by offering a vision of a possible future (be it utopic or dystopic) that critiques the current status quo today (Sargisson 2007). Most prominently, for example, utopias of feminism, ecology, and self-management both in the spheres of work and the day-to-day life currently offer a united opposition toward capitalism, neoliberalism, and patriarchal structures today. These utopias are “no places” in two senses: they lie on the horizon – or as Bloch puts it in the “Not Yet” and they are not fully imagined. By focusing on one issue or voice at a time (rather than a whole social system) it allows for a plurality of voices and ideas that grants it the fluid nature it needs to overcome anti-utopian criticisms of the underserving Platonic ideal previously discussed.

These are the utopias (and dystopias) that we are most familiar with today. Kim Stanley Robinson’s *Mars* trilogy (1993–1996), Ursula Le Guin’s *The Dispossessed* (1974), Philip K. Dick’s *The Man in the High Castle* (1962), and Orwell’s *1984* (1949) are but a few examples of the vast repertoire of works written since the second half of the twentieth century that attempt

to showcase different ways of being that are possible within our own timeline, and seek to inspire and catalyze change. Crucially, then, utopias are about the present, they necessarily come from a place of discontent with the now and use the imagined possible future as a tool to inspire change or promote a wider social transformation.

Living Utopias

Spurred on by what Raza and Kurnik (2012) have called a “fundamental crisis of representative politics,” critical utopias have spilled over into the sociological imagination, inciting change and encouraging political uprisings on all sides of the political spectrum. The imaginings of a different world set in the future incites us to hope (or despair in the case of dystopias) and act toward this hopeful future, approximating it by closing the speculative gap between the present and the possible future through the pursuit of bringing the possible into actuality (Bryant and Knight 2019). The global #Occupy movement, for instance, emerged as a critical response to the global financial structures that created the 2008 financial crash. This inspired a collective utopian imagination of radical rupture with the past financial status quo in favor of a future free of global capitalism in which compassion and direct democracy would prevail (Nugent 2012). Occupiers looked to distance themselves from what was and what is, orienting themselves toward a temporal horizon that compels participants to imagine the future full of hope, promise, and possibility. Following the structure of a critical utopia, this sociopolitical terrain of that imagined future is yet to be fully defined, however the main object of critique is clear, and glimpses of the possible utopian future emerge, as one Occupier stated: “the best part of the occupation is the small slice of utopia we are creating... participatory assemblies...community building...horizontal collaboration” (Ibid.: 281). The imagination of this possible alternative utopian future works in two ways: as a social critique of the present and as a way of approximating the future through the efforts of bringing this possible into actuality.

Alternative economies form a large part of living utopian projects today, in particular in relation to property ownership. Sargisson’s (2007) extensive research across 60 alternative utopian communities in the UK and New Zealand highlights the central importance of fair economic management for the self-perpetuation of these communities. Each of these intentional communities she visited practiced an alternative economic system of ownership, exchange, and direct democracy, often tied to specific ideologies or utopian visions that were collectively shared. These communities serve as isolated islands of experimentation in which utopian visions of the future (such as a money-free economy based on More’s original *Utopia*) can be explored and inhabited. In this way, the utopians are rejecting the present conditions of the world which they find unacceptable and demonstrating that a different future is possible, much in the same way as Robert Owen intended with New Lanark. This embodiment of an alternative possible future once again aims to encourage and incite change in the present by proving its viability.

Alternative economies and financial systems form part of a larger global utopian movement for radically different politics born from a discontent with the current status quo. The Scottish independence movement, for instance, was born from a fundamental discontent with the way Westminster politics were being carried out in Scotland and the democratic imbalance that exists between the two countries. As an alternative, a new imaginative utopian future has been proposed, the Scottish National Party selling a vision of an independent Scotland as a prosperous, fair, thriving nation (Manley, 2019). Their slogan “Another Scotland is Possible” encapsulates Vieira’s (2010: 6) vision of utopia as “a desire for a better life caused by a feeling of discontentment towards the society that one lives in” in which this possibility of “a better place” becomes tangible through political action and the possibility of another independence referendum in the horizon.

More controversially, new debates on eugenics and gene editing have been dominated by both utopian and dystopian visions of the future. Eugenics ideas (i.e., the idea of improving the

gene pool of a population) were originally advocated by scientific and religious leaders at the turn of the twentieth century, driven by utopian ideals of social reform (Raz 2009). These ideals however later on lead to anti-utopian atrocities made in the name of progress by authoritarian regimes, most notably – but not exclusively – with the Nazis and their pursuit of the improved Arian race. Similarly, eugenic practices were carried out by countries not usually associated with authoritarianism, such as the USA and Sweden who for decades sterilized tens of thousands of mentally ill citizens. It is unsurprising then that much like Popper (1962) most are wary of utopias which speak of the human and improvement of the “race.” However, with the emergence of new technologies such as gene editing a relatively new utopian eugenics movement has emerged. Hinging on utopian outlooks of Transhumanism, it argues that it is an “intellectual and cultural movement that affirms the possibility and desirability of fundamentally improving the human condition through applied reason, especially by developing and making widely available technologies to eliminate ageing and to greatly enhance human intellectual, physical, and psychological capacities” (Ibid. 608). The utopian vision they sell is one of a future free of any suffering brought on by the human body and argue that gene editing eugenics is the path that will lead us to this idyllic future. As what is possible evolves, so do alternative utopian visions of the future.

Conclusion

Utopia has proven itself to be a vast, complex, and slippery concept to capture, with scholars often disagreeing on narrow definitions and categories of inclusion. However, all utopias at their core deal with the idea of the possible, encapsulated in a “desire for a better life.” In this way, whether these utopias exist in another space or time, with different backgrounds and purposes, they will always seek to incite a feeling of possibility (be it elsewhere or in the future). Moving away from the idea of utopia as a static blueprint for a “perfect” society, contemporary utopian studies recognize the fluid and critical

nature of utopias, and the flexibility that the concept of a “place that is no place” offers. Through not just fiction, but political theory, revolutionary movements, arts, and sciences utopias do not only imagine a better world but tell us of people’s concerns with the now and their desires for tomorrow. By critiquing the present through the presentation of possible alternatives they inspire us to question and change the status quo, striving for this “better way of being.” This fluid definition of utopia allows for them to grow and evolve, adapting to the changing paradigms around them. As what is possible changes, so do our fears and desires, and therefore so does utopia.

Values

Angela Uchoa Branco
Institute of Psychology, University of Brasília,
Brasília, Brazil

Abstract

The term *values* designates a psychological construct that plays an important role in motivating human actions and interactions with the world throughout individuals' life trajectories. Values operate at both individual and social group levels, acting as a sort of lens for interpreting the world—affecting one's perception, thoughts, feelings—and as a powerful motivational force for encouraging specific actions. Diverse theoretical perspectives conceive of values differently, focusing on their different roots and qualities. Due to the immense complexity of the psychological processes implied when we refer to values, the traditional approach of psychology has been too limited with most investigations carried out from a cognitivist quantitative methodology that simply measures the frequencies of particular pre-established values in specific populations. Pre-defined categories of fixed and mutually exclusive values, however, cannot actually explain the highly complex, plural, multifaceted, and intricate quality of human motivation. In this entry, some new venues to study and theoretically conceive of the issue

will be explored, opening up possible perspectives to the investigation of the ontogenesis of values and their development in specific socio-cultural contexts from a systemic cultural approach in psychology.

Keywords

Values · Moral values · Goals · Goal-orientation · Motivation · Beliefs

Introduction

The relevance of the subject—human values—has been acknowledged since the dawn of humankind. The notion of values—meaning what is worth achieving or not, i.e., preferences, goals, and purposes—has been proposed to make sense of people's actions and reactions from early philosophical attempts to find some order or regularity in the dynamics of human practices and experiences. Many Greek philosophers struggled with this peculiar psychological construct aiming at understanding the reasons—often not rational at all—that lies behind human actions and interactions. Among them, the work of Aristotle certainly stands out because he wrote at length on this topic with an emphasis on the right pathways and principles to orient the incessant human search for happiness alongside the role of virtues to achieve worthy lives. Since such old thoughtful inquiries about what motivates human actions—

beyond immediate demanding circumstances, or responses to basic physiologic needs—concepts like human *needs* and *values* have developed from different philosophical and scientific viewpoints or frameworks. The concepts of needs and values emerged as psychological constructs, which proposed to provide reasonable “explanations” about *why* human beings behave as they do, displaying distinct patterns of behaviors in specific contexts either with a certain degree of consistency or, not rarely, with contradictory courses of action.

Many of the idiosyncratic and sociocultural patterns of human interactions with self, others, and the world at large have attributed to distinctive traits of personality as well as the fact that people, individually or as a social group, tend to hold specific values, i.e., hold dear the attainment of certain objectives or general goals in their life experiences. However, due to the immense complexity of human phenomena and psychological processes, the simple inference and nomination of a particular set of values—typically found in people with certain personality characteristics or members of a certain social group—cannot actually explain the highly plural, multifaceted, and intricate quality of human motivation. As a result, instead of explaining why people behave in certain ways, the traditional quantitative studies of values—conducted by social and cross-cultural psychologists—can only function to generate a descriptive picture of human preferences. This may lead researchers to equivocal conclusions, which are explained in the following sections. This is becoming increasingly evident as the substantial complexity of this issue becomes more salient. Hence, now there is a growing need for new venues and possibilities to qualitatively investigate and analyze values which will, hopefully, lead to a more solid and all-encompassing theoretical base.

The matters addressed in this entry will be particularly for those interested in possible and alternative routes for investigating values, here approached from a dialogical cultural perspective that builds on the role of imagination, social interactions, human development, and cultural resources for possible future practices in the contexts of contemporary societies.

The following sections underline the necessity of innovative approaches to investigate human values by presenting and discussing some of the major aspects and dimensions of the phenomena. The work presented here takes a critical view of the traditional theoretical scientific framework still found in contemporary psychological literature about values (Knafo et al. 2011), which defines values as a “cognitive construct” (Oyserman 2015), as an “internalized social representation” (p. 37), exactly in the same way psychological mainstream conceives and analyzes the topic. Alternatively, this entry explores other conceptual-theoretical perspectives more akin to the multidimensional nature of human motivation, and especially analyzing the power of affectivity over the ontogenesis of values along individuals’ life trajectories. According to this new perspective, the dimension of affectivity, expressed at the diverse hierarchical levels of its regulatory function upon human psyche, plays a central part in the genesis and development of individuals’ and social groups’ values. The first section provides a brief historical account of the ideas of some philosophers and sociologists. The next section moves on to critically scrutinize the construct as it has been used and studied by social and developmental psychologists until the present day. The next sections, which propose a different viewpoint upon the subject of analysis, then open up the theoretical account on the issue of values to a multidisciplinary, complex, and systemic approach. The last section explores the topic further as it moves into the realms of the possible, the imagined, bringing into the domains of psychology—conceived as a normative or moral science (Brinkmann 2009, 2011)—the discussion about future expectations and alternatives. This discussion mainly concerns the development and implementation of new social practices concerning values, as well as the cultural development of both people and society.

Ethics and Values

The term values had multiple definitions depending on the historical time and on the

epistemological-theoretical background of the author. From the domains of theology, philosophy, art, and literature, the notion of values emerges as a stance for guiding directions of human actions; they are found in all the cultural narratives ever produced in history. The struggle between what is right or wrong, good or bad, and the accompanying implication of various forms of moral judgments, social preferences, rewards, and sanctions pervades our experiences and narratives all along the journey of humanity.

The Ancient Greeks were not the first to reflect upon issues of human motivation, but, certainly, their historical legacy in the realms of science and philosophy contributed to our present day understanding—though still poor—of the subject. Among others, Aristotle's profound elaborations over the best ways to achieve happiness and to live a good life—a life worth living—by behaving in accordance to a certain number of virtues, has a special influence. Virtues—meaning excellence in the performance of any action—such as truth, loyalty, courage, among others, were considered absolutely relevant to the experience of happiness, and therefore should be cultivated and promoted among human beings.

Sofocles' contribution to the topic was wisely studied by Freitag (1997) who analyzed his play *Antigona*. She demonstrates how artfully the playwright exposed the moral dilemma faced by the protagonist. Antigona transgresses the law in order to bury her dead brother, following the moral values and customs determined by her family traditions. Caught in this transgression, the king judged and condemned her to death. All facets of this moral tragedy are meticulously played out in Sofocles' plot, and thoroughly analyzed and discussed by Freitag (1997). After all, what would be the right thing to do? What sanctions, if any, should Antigona face for her transgressive action? Freitag's (1997) conclusion in terms of terminology is that when the protagonist follows her family values, she acts according to the domain of Morality (*mores*, in Latin), and does this in opposition to the social norms—instituted laws—of the city, in other words, against the rules of Ethics (*ethos*, in Greek). Freitag's arguments are strong, and follow Hegel's terminology

attributing *morality* to the personal (or family) level, and *ethics* to the institutionalized norms and rules of the society. This issue is relevant because many dilemmas display similar oppositional directions, which, instead of being a dichotomy, represent instead the inherent duality occurring whenever oppositional forces create motivational tensions. These tensions, consequently, demand innovative thinking and actions. Tensions among values are widespread. I will return to this subject later when proposing a tentative theoretical model to explain some aspects of the ontogenesis and psychological dynamics of human values.

Over the last three centuries, many philosophers and, more recently, sociologists, have dedicated their attention to the subject of values mostly addressing the dimension of ethics and morality. Even though the meaning of “values” from a psychological perspective also extends further away from morality and ethics (values referring to aesthetic, political preferences, human traits, etc.), usually the notion of values is impregnated with positive or negative valences such as good *versus* bad, right *versus* wrong. Among so many worth mentioning, Rousseau, Kant, Hegel, Weber, Parsons, and Durkheim stand out because of their seminal ideas.

However, for reasons of concision, this section will address three contemporary philosophers or social theorists who have inspired interesting thinking on the topic. They are Jurgen Habermas, Alasdair MacIntyre, and Charles Taylor.

Habermas (1991) developed a *communicative action* theory in which he elaborated on his discursive ethics from a dialogical, intersubjective viewpoint. For him, language and communication played a central role in evaluating different perspectives on the issue of ethics and morality, arguing for the encouragement of sociability, solidarity, and cooperation among interacting individuals. In other words, norms and values would arise from the dialogue among diverse perspectives, voices, and rational arguments put forth under a democratic social agreement. His ideas, although dialogical, remain in the domains of cognition, and do not refer to the power of emotions and motivation in the genetic processes

of values development. The issue of power relations among people, as well, was not explored by the philosopher.

Charles Taylor (1992) built on the subject of values and morality from a hermeneutic approach in philosophy. For him, meaning making resided at the center of human existence. Insisting on the topic of agency, humans should be conceived as self-interpreting beings. From his narrative approach to human experience, he alleged that individuals hold some ethical values to be worthier than others, and proposed a moral theory that transcends subjectivism. Following Aristotle, he admitted the existence of good, since people experience a kind of trans-subjective source of the good. Therefore, certain values are common to all human beings, and it is possible to infer for the existence of fundamental needs and values beyond those merely subjective or relative to cultural preferences. According to him, to conceive ethics as disengaged or neutral is unthinkable, for it should be seen as dialogical and encompass values such as tolerance, human rights, and democracy. He approaches the domain of psychology as he claims that one's sense of self and life itself depend on individual's values.

MacIntyre (2007) also defends the objective grounds from which ethics and moral values emerge. For him, social rules alone do not do the actual job of providing social norms, for the latter derive from substantive values. Values, on their turn, are not simply good because they are desired, but because they provide us with good (moral) reasons to be desired, whether or not one actually desires them. He argues that the moral dimension is the only way to make sense of the world, and that words and language, i.e., meanings, are necessarily moral because they are, in fact, value-terms. To the theorist, meanings emerge from social practices, and the reasons for people's actions are located in the moral order of such practices. In short, for MacIntyre, all psychological phenomena are at bottom normative and value-laden. This makes the study of values an essential endeavor for all social sciences.

After this brief reference to some of the philosophical roots of the concept, the following section focuses upon the ways psychology has

traditionally investigated the topic. After that, alternative theoretical accounts of the issue and possible perspectives for the future will be provided.

Values as Psychological Constructs: A Critical View on Cognitivist and Quantitative Approaches

Contributions to the study of human values in psychology come, in the main, from two different epistemological and theoretical traditions. The prevalent tradition permeates the literature of social psychology and essentially aims at the description and evaluation of the frequencies of pre-established value categories detected in different people and environments, according to a quantitative methodological approach. The other trend in psychology literature consists of the constructivist analysis of Jean Piaget and Lorenz Kohlberg, both developmental psychologists, whose theoretical ideas, inspired by the philosophy of Immanuel Kant (1788/1994), addressed the topic of moral development.

Social psychology literature referring to human values is impressively vast (Oyserman 2015). Well-known social psychologists as Rokeach (1973) and Schwartz (2012), among many others, have elaborated cognitively oriented theories and produced huge amounts of data concerning what kind of predetermined values categories were more frequent among certain individuals and groups. Making use of sophisticated statistical procedures, they came up with clusters of values that tend to show up together, or be in opposition to one another. With the recent advent of cross-cultural psychology, many researchers have carried out numerous empirical studies to compare those values categories that prevailed in different countries or social groups (Knafo et al. 2011). Data collected by such studies allowed some researchers, for example, to divide the world into those who are individualistic (axiological profile typical of Western industrialized societies) *versus* those who are collectivistic (typical of traditional, developing countries), to the point that Triandis (1995) anticipated a future clash of

civilizations due to such opposite cultural values. One of the major problems, though, is that most countries, in the contemporary world, are multicultural and heterogeneous, and assumptions about countries' or social groups' cultural homogeneity can be misleading. What is the point in comparing them, anyway? This tells nothing about how values emerge and develop.

Instead of reducing the phenomena associated to human values to a search for discrete, predetermined, fixed, and independent categories inferred from variations of Likert-type rating-scales, questionnaires and tests, why does psychological science not invest in the investigation of how values develop in specific cultural contexts, and what factors contribute to their ontogenesis? Why does psychological science take values for granted, and reduce such complex phenomena to a simple description of fixed categories? What we see instead is a large amount of effort but little actual explanation about those multilevel and interdependent factors, processes, and mechanisms influencing and promoting the emergence and development of specific human values in specific cultural contexts.

Piaget and Kohlberg, in their turn, were particularly interested in the moral development of human beings, which necessarily encompasses the development of values. In accordance with a constructivist cognitivist approach to psychology, both analyzed the processes of change occurring in children and adults' verbal judgments regarding moral dilemmas. Their analyses, though, considered specific stages of moral development. For Piaget (1994) children move from a stage—i.e., a specific structural cognitive mode of organization—of anomia (no rules) to a stage of heteronormia in which all moral principles come from authorities (parents, teachers). Then they move (or may not move) to a stage of autonomy, in which they judge for themselves if a certain action is right or wrong. Kohlberg (1984) expanded the number of stages (or substages) to six, the individual, hopefully, moving from a stage of hedonism to conventionalism to post-conventionalism. Even though Piaget and Kohlberg consider the active and constructive nature of human beings, the major limitation of their approach was to

dismiss the central role played by three important factors in the moral development of individuals, namely, social others, deeply affective motivations, and cultural contexts. The theoretical framework presented next highlights specifically these factors from a multilayered, systemic perspective.

Values and Culture: A Sociogenetic, Constructivist, and Systemic Approach

Cultural Psychology's view on the topic is systemic, sociogenetic, and dialogical. It also addresses the issue of values taking into account that psychology is, as Brinkmann (2009, 2011) proposes, a moral science. According to the author, "(1) we have a capacity for perceiving 'oughtness' as part of the world, (2) given that rules and norms order social life, there seems to be an inherent 'factual normativity' in our lives, (3) human functioning in general cannot be understood in value neutral terms, and (4) value-terms cannot be exorcised from our vocabulary, at least not from the part of our vocabulary that designates action, thinking, and feeling" (2009, p. 2).

The arguments presented by Brinkmann (2009, 2011) concerning the very nature of psychology are powerful and compatible with the views of both Taylor and MacIntyre. As human beings are inherently social (Maturana, Simmel), some basic moral values tend to be relatively universal (despite the oxymoron), meaning that, in different degrees or formats, they may be found in numerous cultures all over the world. In other words, even in cultures with diverse sociocultural configurations and actual practices social groups persist and develop, which points to general social norms of moral kind against, for instance, indiscriminate homicides, lies, and general practices of deception. From a Cultural Psychology perspective, it is possible to admit the existence of such basic moral guidance with diversified nuances, as well as acknowledge the fact that each culture holds dear many other different values, which generates a singular set of values orienting most of its social practices. Anthropological studies provide the scientific community with several source of evidence concerning both findings, indicating the existence

of diversity as well as the worldwide presence of some basic values necessary for the cohesion and continuity of the group. This issue is worth exploring further, but due to the scope of this entry, it is necessary to move to some possible venues for the investigation and theorization about the ontogenesis of values, focusing upon how they emerge and develop in different people and contexts.

As previously stated, values are general guiding principles for human conduct and are directly linked to the dimension of motivation. Valsiner, in his seminal book *Invitation to Cultural Psychology* (2014), proposed an Affective-Semiotic Regulatory Model of the *psyche* that helps to clarify the role of affective-semiosis processes in giving rise to hypergeneralized affective-semiotic fields that he qualifies as human values. According to the author, cultural psychology conceives human development and *psyche* as emerging from human interactions and permanent meaning-coconstructions that occur during social practices and communication. Consequently, affective-semiotic processes produced in cultural practices play a fundamental role in human psychology. Valsiner elaborated a hierarchical affective-semiotic regulatory model of human conduct that starts from a physiological level, up to the emergence of emotions (characterized by verbal labels), and all the way up to hypergeneralized fields located at a post-verbal level, which display the role of guiding the person's mind and actions. Values, and their counterpart—prejudices—consist of such hypergeneralized affective-semiotic fields guiding the individual's perceptions, interpretations, thoughts, feelings, and actions directed to self, social others, and the world at large. Even though powerful, the nature of values is fuzzy, not fixed, and, as they emerge from each person's experiences along life-trajectories, they can be multiple and contradictory. That is, they can integrate or oppose to other values generating tensions that can, eventually, be smoothed out by interpersonal and intrapersonal dialogues. Or else, tensions can create difficult and hurtful dilemmas for the person. It is worth mentioning, though, that tensions, possible dialogues, or

negotiations among opposing values often take place in the absence of individuals' awareness. This makes the struggle to face dilemmatic situations even more complicated. However, an important question remains: how values emerge in the first place?

As a child develops, certain personal goals—or goal-orientations—contribute to configure significant, special, affective-semiotic motivational fields that either weaken or become empowered as time goes by. The investigation of the pathways through which such processes take place, then, allows the researcher to unravel the routes taken by the ontogenesis of values, identifying those multiple factors operating as catalysts to give rise—or to lessen—specific fields instead of others. For instance, depending on the developing person's experiences of socio-affective relations in determined cultural contexts, certain affective-semiotic fields become progressively hypergeneralized and more powerful to motivate the person's actions in certain situations. Take for example the case of a child constantly reminded and praised—in her interactions with parents and peers—that looking good or beautiful is her best quality or virtue as a person. The odds of this child developing a significant semiotic-affective field related to “beauty” are relatively high (Roncancio-Moreno and Branco 2017). For sure, other factors—deriving from other experiences—may interfere, but there is an actual possibility for the child, in the future, to consider beautifulness as a value to pursue. Hence, if it is possible to explore and investigate how values and prejudices emerge along one's life experiences with significant social others, it is also possible to understand how to deconstruct prejudices and promote values changes. This would contribute to meaningful transformations to improve individuals' health and well-being, as well as to ameliorate or enhance the quality of life in our societies. As by now is evident, the perspective here adopted does not attempt to remain neutral, for it derives from an epistemological-theoretical framework that conceives psychology as a moral discipline.

Another key aspect of this approach is to bring to light the role of the imagined future in

configuring powerful values. Not only people's reconstructed memories of the past (Wagoner 2016), but especially their anticipations of the future, play a strong role in the emergence and development of their values. The perspective to attain or to reach certain significant goals in the future keeps the person motivated to feel, think, and act in ways that may facilitate such achievements (Branco and Oliveira-Silva 2019). As a result, values end up helping to configure specific I-self positionings that dialogue with each other within the context of the person's dialogical self (Hermans and Hermans-Konopka 2010) or dialogical self-system (Branco 2016). The reference to the dialogical self is appropriate to underscore the relevance of values in the *very* construction (coconstruction) of the human *psyche*.

New Venues for Research and Practices to Promote Moral and Democratic Values

In terms of research, the natural consequence of assuming a systemic, affective-semiotic cultural approach to values phenomena redirects investigative efforts toward a qualitative methodology, in order to unveil important aspects involved in the ontogenesis of values within specific cultural contexts. Moreover, since each individual's life trajectory is unique, it is necessary to invest in carrying out innovative forms of research to make sense of the general processes that participate of values ontogenesis. From the alternative perspective here presented, only processes can be generalized, for it is useless to search for universal tendencies or "mean" results (provided by statistics) that do not actually apply to specific cases. One possibility is to conduct longitudinal studies employing multiple, creative, and innovative methodological procedures so that all possible influencing factors can be identified and analyzed from a systemic approach. This is the only way to understand why family members or peers can be so different from each other even despite living in relative similar contexts, or sharing apparently similar experiences. Some research procedures

to investigate the ontogenesis of values can be interviews with subjects and relatives, filmed and direct observations in natural and semi-structured activities, focus groups, images production and interpretation, and so on. Microgenetic approaches also consist of a productive venue to knowledge construction about the subject under investigation (Abbey and Diriwachter 2008).

With reference to the construction and implementation of possible social practices, some reflexive thinking is particularly timely. Individualism has been traced in the history of ideas (Taylor 1992), and became progressively pervasive with the advance of modernity and globalization (Lash 1985; Sennett 2013). According to Kagitcibasi (2005), "the individualistic worldview tends to be seen as the norm and is exported to the rest of the world as the human model to emulate" (p. 405). The author alerts the reader to the dangers of excessive individualism and suggests that psychology has contributed to the exaltation of the individual, unencumbered by any loyalties to others. He argues that even from an evolutionary perspective, the survival value of cooperation and relatedness in humans exceeds that of individualism. To him, contemporary research reaffirms the value of relatedness in post-modern society. Therefore, the search for new venues to investigate and promote moral and democratic values in human societies consists of a possible and necessary endeavor.

The welcome consequence of assuming a developmental and cultural approach to values is, hence, the ability to construct and implement creative ways to foster social change at both individual and collective levels. By acknowledging the role of multiple interdependent factors in the ontogenesis of values, a systemic perspective allows for the development of more efficient efforts concerning social and psychological interventions to encourage or stimulate meaningful changes, by persons' actual engagement in cultural practices of collaborative and solidary kind. A promising context to do so is educational institutions. Aware of the mutual construction of cultural practices and values, educators, with the participation of the school community, can

introduce creative ways of promoting activities where affective-semiotic processes would mobilize reflectivity and the internalization of values of justice and care for the well-being of everyone. Instead of reproducing the prevalent values of individualism and competitiveness, relatedness, cooperation, justice, and solidarity would then become part of the new generations' life projects. This would open new venues for a permanent coconstruction of a better world, a world—following Aristotle's advice—worth living.

Summary

Within the realms of art, literature, and philosophy, values and beliefs held by individuals have always played a major role in making sense of human life. The struggle between right and wrong can be found everywhere, bringing about tensions between opposing values such as individualism, competition, cooperation, and solidarity. Psychology has approached the issue from two different but limited cognitive frameworks: a cross-cultural social psychology approach, which invests in simply measuring the occurrence of predetermined categories, and a constructivist perspective interested in the study of progressive stages of morality. In contrast, the cultural psychological approach provides theoretical and methodological resources to investigate the meanings and factors contributing to the ontogenesis of values, as well as resources to develop strategies to promote social changes according to the democratic and social values held dear by our civilization. In conclusion, the issue of values is complex, multifaceted, and has to be investigated and dealt with from an open, systemic, and interdisciplinary perspective. This seems to be the only way to promote the achievement of possible and welcome futures for humankind.

Abstract

The touchless economy of the pandemic era includes a network of virtual communities in which people participate as they conduct their everyday lives in a low-exposure-risk fashion. To help understand and put these communities in context, this entry describes a typology of virtual communities adapted from Porter (2004). The five elements of the proposed typology include (1) purpose (content of interaction), (2) population (participants in the interaction), (3) platform (design of interaction), (4) place (location of interaction), and (5) profit model (return on interaction). This five-element typology facilitates recognition of essential elements and differences between the many virtual communities that are becoming part of people's lives in the pandemic era and helps frame and put in context (a) likely new practices and technology applications and (b) new topics for future post-pandemic research in the social, business, and computing sciences.

Keywords

Platform interaction framework · Virtual communities · Online platforms · Touchless economy · Pandemic · Covid-19 · Typology · Sharing economy · Zoom meetings

Summary

An unexpected consequence of the Covid-19 pandemic has been the accelerated diffusion of virtual communities. What started in gaming, social media, virtual worlds, and e-commerce has been increasingly pushed into day-to-day business and education activities. Indeed, the everyday world has become increasingly virtual, and it is fair to say that most people reading this entry now live in a hybrid world – a blending of virtual and in-person interactions.

Globalization has long been argued to foster international trade, division of labor, specialization, efficiency, and economic growth (Smith, 2010), but now one must recognize that globalization also poses a challenge for public health. It is likely no coincidence that the outbreak of the Spanish Flu dovetailed with the end of World War I in 1918 – a time when international exchange of goods, ideas, and people reached a new height (Saunders-Hastings and Krewski, 2016; History.com, 2020; Wikipedia, 2020a,b).

A key mitigation measure involves replacing in-person interaction with virtual interaction in offices, factories, warehouses, schools, and even stores. This is made possible by the Internet and many new online platforms. Indeed, interaction in virtual communities is central to what has been called “the touchless economy” (Wu, 2020, p. 1):

The touchless economy comprises the economic activities that remain possible without close physical interaction between people: the online meeting, the live-streamed yoga session, the virtual conference, the drop-off delivery of groceries and other physical goods. As it stands, this is pretty much all the economy we've got.

To provide insight into the touchless economy, the current chapter adapts and extends C. Porter's (2004) typology of virtual communities. This typology has been previously applied to virtual

worlds (Messinger et al., 2008b). Our purpose is to extend this typology further to help understand, categorize, and formulate research questions about virtual communities critical to the touchless economy. In particular, we consider how this typology applies to a range of virtual communities that constitute the essence of the touchless economy, including (a) hybrid communities supported by virtual meetings (directed toward whatever goals a group maintains), (b) consumer and provider communities in the shared economy, (c) e-commerce, and (d) education, as well as (e) leisure activities, including social networking, gaming, and virtual worlds.

We argue for the relevance of this typology by showing how its five elements provide a framework for categorizing and understanding differences in the functioning of many kinds of growing virtual communities. We then describe how such virtual communities are playing pivotal roles in the touchless economy. We lastly argue that these five elements can help structure directions of inquiry into the *possible* – to help identify new applications and research questions. In this way, exploring the functionality of various virtual communities, organized according to this typology, is highly topical for an entry into the *Palgrave Encyclopedia of the Possible*.

Section 1 below describes key antecedents of virtual communities in the touchless economy. Section 2 advances our suggested typology of virtual communities. Section 3 uses the typology to help categorize and put in perspective key virtual communities in the touchless economy. Section 4 interprets the growth of virtual communities in the touchless economy in light of the dimensions of our typology. It also identifies directions for research in social, business, and computing sciences, and possible new applications and technologies. Section 5 concludes.

Antecedents of Virtual Communities in the Touchless Economy

“A virtual community,” according to Porter (2004), “is defined . . . as an aggregation of individuals or business partners who interact around a

shared interest, where the interaction is at least partially supported and/or mediated by technology and guided by some protocols or norms.” Some of the earliest virtual communities began in small groups of interconnected computers in work environments and in gaming, then increasingly in social computing, and subsequently in day-to-day economic activities.

Gaming Early digital connectivity was carried out in small groups and Local Area Networks (LANs), where many terminals were connected by timesharing to a mainframe computer often for business applications (billing and ordering systems) and research computing. Digital connectivity also arose in arcade and home-released games, with platforms emerging such as the highly successful Nintendo Entertainment System.

Combining some of the functionality for gaming and social networking, Internet-supported gaming emerged both as discrete gameplay sessions with fixed beginnings and ends, and open-ended persistent virtual spaces – or “virtual worlds.” The earliest shared virtual worlds are sometimes overlooked because these Multi-User Dungeons, or MUDs, were worlds only encountered through text (Bartle, 2009). In the 1990s, graphics were added to the experience. The most commercially successful entrant in this genre was *World of Warcraft* (2004), for which over 100 million accounts had been made by 2014 (Sarkar, 2014). An essential feature of this genre, which became known as Massively Multiplayer Online Role-Playing Games (MMORPGs or MMOs), was that *shared* servers meant that everyone logged into a given virtual world server can see and interact with each other in real time.

Around the same time, there was also an interest in developing virtual worlds that were not steered by the rigid character archetypes and fixed plotlines of MMORPGs. Instead, these open virtual worlds centered upon self-directed exploration. *Second Life* is perhaps the best-known example of an open virtual world, where “there is no manufactured conflict, no set objective.” Participants can create and trade objects, elaborately customize the appearance of their

avatars, and shop with a local currency, the Linden dollar, convertible with US dollars (Kalning, 2007).

Gaming, when integrated with sites like Facebook, became deeply entangled with players' lives, as in the "casual" titles such as *Farmville* and *Candy Crush*. Augmented reality games subsequently emerged, such as *Pokémon Go* introduced in 2016, that integrated virtual objects, such as Pokémon creatures from the Nintendo series, with real settings such as a city street, a park, or the inside of a restaurant (Goldberg, 2016).

Business and Social Computing The Internet allowed for scalable social experiences without the need to share physical proximity or a dedicated line. As the Internet gained greater consumer acceptance and broadband access led to faster, always-on home connections, connectivity blossomed for business, social computing, and gaming. People could do their business computing at work or home and could connect via email and the World Wide Web to others both within and outside the company. People could now shop on e-commerce-enabled online retailers. People could also interact with each other in emergent social networks such as Facebook, Twitter, Instagram, etc.

The Sharing Economy A new set of virtual communities has grown around the sharing economy in the last few years. The key idea behind the sharing economy is that the service potential of various durable, intellectual, and other capital resources can be vastly expanded when these resources are shared, with compensation through online platforms, as compared to when the same could only be used by their owners or friends. The "sharing economy" includes ride-sharing (e.g., Uber, Lyft) and equipment/car rental (e.g., Quupe.com); hospitality, hotels, and accommodation (e.g., Airbnb); online media and content/media streaming (e.g., Spotify, Netflix); on-demand staffing (e.g., TaskRabbit); and crowd-based financing. Recent growth in these sharing economy spaces has been rapid. For example, the combined market value of Uber, Lyft, and Airbnb was around \$106 billion as of

July 2017 (Craggs 2017). "The sharing economy is set to reach 335 billion by 2025 ...; [it] will grow by a staggering 2133% in just 12 years; ... over 86 million Americans will use the sharing economy by 2021 [and] China's sharing economy is expected to grow 10-15% in 2021." (Petrov, 2021, p. 1).

The above narrative summarizes a selection of developments of various forms of virtual communities that have grown in the last three decades to which the typology, described next, applies.

Typology of Virtual Communities

This section considers a typology that promotes further understanding, study, and application of virtual communities in the touchless economy. Following Porter (2004), this typology has five elements. Messenger et al. (2008a) extend this typology to virtual worlds, gaming, and social networking. The current section builds on this latter paper, extending this typology to describe (a) virtual-meetings-supported communities, (b) the sharing economy, (c) e-commerce and brand communities, and (d) educational communities.

The five elements of the typology are as follows:

1. Purpose (content of interaction): At the heart of a virtual community is the purpose of interaction. The purpose specifies both the content and outcomes of interaction. The content consists of the specific type of information communicated in the virtual community. The outcomes can include shared information, entertainment, the facilitation of joint work or learning, or trading and commerce between participants.
2. Population (pattern of interaction): It is critical to consider distinguishing characteristics of the target user market. Characteristics of the population include the size of a group and the types of social ties.
3. Platform (design of interaction): The technology platform for a virtual community is central

to facilitating interaction: The design features of the platform influence the kinds of information shared, the kinds of activities engaged in, any decisions made, and any work done. A key element consists of whether communication is synchronous or asynchronous. Platforms can support connectivity through PCs on the Internet, mobile devices, and various forms of gaming devices.

4. Place (location of interaction): This element specifies whether the interaction is completely or only partially virtual (a hybrid community) and whether the participants are collocated or geographically dispersed. The countries, cities, or regions covered can shape the nature of interaction.
5. Profit Model (return on interaction): The profit or revenue model describes how the virtual community is financially sustainable. The form of revenue generation is potentially rich and diverse.

The logic of the typology is straightforward. A virtual community needs a reason for being – a **purpose** around which the participants interact. A virtual community must connect a **population of participants**, with an interest in the common purpose. A virtual community must have an online **platform** through which to interact, either using computers, smartphones, or gaming consoles, that also supports the functions of the intended purpose. And the virtual community will operate in a particular region, a **place**, which could be global, a country, a region or city, or a dedicated local network within a single building or campus. Lastly, there must be a **profit model** or revenue model to help cover the costs of maintaining the platform and paying for any tech and other jobs to keep the community running. Thus, by logical necessity, every virtual community is described by these five “P’s.” As noted by Messinger et al. (2008a, p. 11), “Indeed, the five elements (purpose, place, platform, population, profit model) focus on critical questions that journalists, marketers, and service providers are taught to ask: (1) For what purpose? (2) Who? (3) How? (4) Where? and (5) How much?”

Porter has argued that the five elements of this typology meet five criteria for a good typology, established by Hunt (1991). These criteria are as follows:

- (1) Is the phenomenon to be classified adequately specified? (2) Is the classification characteristic adequately specified? (3) Are the categories mutually exclusive? (4) Is the typology collectively exhaustive? (5) Is the typology useful? In this section, Criteria 1–4 will be used to assess the adequacy and strength of the proposed typology. The final criterion of usefulness is considered most vital in an evaluation of a typology (Hunt, 1991). [Porter, 2004]

The arguments for the first four criteria are not repeated in detail here, since the case has already been made in the context of virtual communities (Porter, 2004). (A brief case has been made earlier that every virtual community must be described by each of the “5 P’s.”) Instead, the next two sections consider the fifth criterion “Is the typology useful?” These sections suggest that the five-element typology is useful for (a) distinguishing, categorizing, and understanding the differences between various kinds of virtual communities, (b) interpreting the historical growth of virtual communities in the touchless economy in the context of the pandemic response, and (c) identifying future applications and research topics involving these kinds of virtual communities.

Categorizing Virtual Communities

There are a wide range of virtual communities covered by variation or differences in each of the five elements of the above typology (see Tables 1 and 2).

Purpose The earliest virtual communities shared information by posting messages and information about a topic to a board, with threads of conversation documented. But these have broadened in myriad ways, including social networking, e-commerce marketplaces, gaming and virtual worlds, the sharing economy, and multifaceted hybrid communities for business, education, and socializing supported by video conferencing and shared digital resources on the cloud.

Messinger et al., (2008a) notes that the purpose of the above typology can be used to apply to social networking, gaming, and virtual worlds (as noted in Table 1). For social networking/social media, the purpose is to disseminate information about oneself, be it text, images, video, or correspondence and messaging, either socially, professionally, or merely sharing information. For online gaming, the purpose is entertainment, and online games foster communities around shared strategic, tactical, and thematic gameplay. For virtual worlds, the purpose is social interaction in a rich virtual environment; the interaction can be completely open, or set in the context of a particular theme, possibly with an explicitly stated gaming objective.

This entry notes that the purpose element of this typology also applies to virtual-meetings-supported communities, educational communities, e-commerce, and the shared economy (see Table 2). (a) For virtual meetings, the purpose is synchronous audio and video communication, often in place of in-person meetings. This can be for business, social, or educational purposes. These communities form in a grassroots fashion, as needed. Often meetings are repeated. And the meetings are supported by a platform, which may be linked to larger ecosystems that include calendars and cloud resources for sharing digital objects and files. (b) In particular, for education, the purpose is learning. But the nature of the resources provided can be multifaceted, including synchronous virtual meetings, and asynchronous

Virtual Communities, Table 1 Typology applied to leisure-oriented virtual communities^a

	Purpose	Population	Platform	Place	Profit model
Games					
Undertale	Entertainment – thematic	One player	PC	Virtual	Fixed fee
Chess	Entertainment – strategic	Two players	Board game	Collocated	Fixed fee
Monopoly	Entertainment – thematic	2–6 players	Board game	Collocated	Fixed fee
Fortnite	Entertainment – tactical	Mass market	Synchronous PC	Virtual, dispersed	Free + extras
Online social networking sites					
LinkedIn	Business networking	Businesspeople	Asynchronous PC	Virtual, dispersed	Free + ads + extras
ArtStation	Themed networking	Creative industry	Asynchronous PC	Virtual, dispersed	Free + subs + extras
ChristianMingle	Themed networking	Religious singles	Asynchronous PC	Virtual, dispersed	Free + subs
Facebook	Social networking	Adults	Asynchronous PC and synchronous	Virtual, dispersed	Free + ads + extras
Virtual worlds					
Sinespace	Open interaction and escape	Mass market	Asynchronous PC	Virtual, dispersed	Free + extras
World of Warcraft	Content-focused play	Mass market	Asynchronous PC	Virtual, dispersed	Fixed fee + subs + extras
Grand Theft Auto Online	Content-focused play	Mass market	Asynchronous PC	Virtual, dispersed	Fixed fee + extras
Webkinz	Content-focused play	Children	Asynchronous PC and synchronous	Hybrid	Ancillaries + extras
Second Life	Open interaction	Mass market	Synchronous PC	Virtual, dispersed	Free + subs + extras

^aFrom Messinger et al. (2008a,b) typology of virtual worlds, with some updates. *Subs* Subscriptions, *Ads* Advertising, *Hybrid* Both collocated and dispersed. Builds on Porter (2004)

Virtual Communities, Table 2 Typology applied to virtual communities in the touchless economy^a

	Purpose	Population	Platform	Place	Profit model
<i>Virtual meetings</i>					
Zoom	Virtualize meetings	Small and large: Groups	Synchronous	Internet	Freemium + prosubscription
Skype	Videophone	2–4 People	Synchronous: part of Microsoft ecosystem	Internet and phone	Freemium + phone account
Google Meet/ Hangouts	Group meetings	2–4 People	Synchronous: part of Google ecosystem	Collocated	Fixed fee + Extras
WebEx	Business meetings	Business meetings	Synchronous	Dispersed	Fixed fee Schedule
<i>Education</i>					
Eclass	Education	Universities	Synchronous	Dispersed	Fixed fee + charge for number of users
Blackboard	Education	Universities	Synchronous	Dispersed	
Zoom based	Open	Diverse	Synchronous	Dispersed	Freemium + premium plans
<i>E-commerce</i>					
Amazon	Marketplace and eRetailer	General consumers	Asynchronous	Dispersed	Direct sales
eBay or Kajiji	Used market Places	General consumers	Asynchronous	Dispersed	Sales fees
Alibaba	Marketplace	General consumers	Asynchronous	Dispersed	Direct sales
WeChat	Socialization and payment	General consumers	Synchronous and asynchronous	Dispersed	Freemium + payment fees
Ele.me	Food delivery	Urban and suburban	Synchronous and asynchronous	Dispersed	Sales fees
<i>Sharing economy</i>					
Uber or Lyft	Rental service	Urban and suburban	Asynchronous	Dispersed	Direct sales
Airbnb	Rental access	Travelers	Asynchronous	Dispersed	Direct sales
TaskRabbit	Themed network	Freelance and business	Asynchronous	Dispersed	Sales fees

^aApplies Porter (2004) and Messinger (2008a) to the domains of the sharing economy, e-commerce, virtual education, and virtual business and social community meetings. Other important platforms, tailored to particular user segments, include Microsoft Teams, BlueJeans, Houseparty, and GoToMeeting.

provision of files, including lectures, readings, notes, and other digital learning objects, including breakout rooms. (c) For e-commerce, the purpose is buying and selling, and creating a virtual marketplace, which can include provision for delivery and service. (d) For the sharing economy, the purpose is to provide other people access to an asset, often through some form of service agreement or renting. This has the advantage of extending the usefulness of a durable good to many people (rather than keeping it in storage for a single owner to be used only occasionally).

Population (of participants/people/parties)

The population includes all members of the virtual community. The largest group, particularly for social networking, is the users. But for commercial virtual communities, providers of services and products are also very relevant. And in certain cases, the institution or company providing the marketplace is a separate participant. Different communities' participants are also typically characterized by age, gender, target-market, or content focus or can be open and/or have a mass market orientation.

Platform There are many types of platforms devoted to particular purposes being served by virtual communities. Different platforms apply for video conferencing, different forms of e-commerce, and sharing economy communities for ridesharing/ridehailing and online bed and breakfasts. This is a rich topic suited at the technical level to computing science, but with profound societal and business implications.

Place One might think of the place for social networking is global, and similarly the sharing ecosystem Airbnb is international, but ridesharing systems like Uber or Lyft are inherently applicable for particular cities where the system is present (and permitted to operate by municipal authorities). And even social computing is limited by language, and with imperfect translation functionality, social networking may apply differently to particular linguistic regions. This is an advantage for WeChat, as the largest social media platform in China with over a billion monthly active users (which many users call the “Chinese Facebook”) operating in China, and with strong functionality in Mandarin and English. Moreover, political restrictions can limit the place for a social community. For example, Google does not operate in China, after some disagreements between these two parties, and its apps do not apply there and so are substituted by local apps in China (e.g., Youku in place of Youtube). Also, the logistics of physical distribution, which may go with forms of e-commerce virtual communities, can influence the geographical extent of the Amazon ecosystem versus Alibaba’s Taobao ecosystem.

Profit Model This element of the typology can include whether participation in a community is supported through (1) a single purchase price or registration fee (i.e., fixed fee); (2) fee per use (i.e., variable fee); (3) subscription based (and on what basis subscriptions are made); (4) advertising based; (5) pay-as-you-go extras (virtual assets including clothing, land, and software); and (6) sale of ancillary products, such as real stuffed animals and accessories, which are accompanied by passwords for accounts in virtual worlds where virtual versions of the products enable combined

real and virtual play. Some free services, known as “freemiums,” or some base level of service is becoming expected by many community participants. The community may be supported in the background by some advertising-based system or analytics information-based market research service about user preferences and proclivities.

Of particular interest is that some of these virtual communities have their own dedicated currency. WeChat Pay and AliPay, which are supported at the consumer level by smartphone and QR code technology, are more widespread in China than credit card systems, or systems like PayPal or accounts on Amazon. Facebook is spearheading a consortium of western tech companies to create the Libra as a similar online currency. These currencies, and accounts for the associated companies, are particularly suited to facilitate the logistics of the profit model of the virtual community. There are great potentialities of related systems, such as cryptocurrencies (based on block-chain technology).

Overall, Table 1 provides a broad summary of how this typology can help to distinguish between leisure-oriented virtual communities in the areas of gaming, online social networks, and virtual worlds. Table 2 summarizes how this typology helps describe, categorize, and distinguish between communities in the workplace, education, e-commerce, and the sharing economy.

The next section demonstrates the usefulness of the typology to help interpret the historical growth of virtual communities in the touchless economy in the context of the pandemic response.

Virtual Communities and the Touchless Economy

The pandemic has served as a catalyst for the growth of many types of virtual communities that form the backbone of the touchless economy. Of course, people facing quarantine have increasingly turned to the types of virtual communities described in Table 1 for leisure activities, as a diversion (Harris, 2020). But perhaps more

importantly, the need to mitigate contagion in the essential activities of life led to the growing use of virtual communities for workspace interaction, education, and e-commerce (described in Table 2 above). The pandemic has also had a dampening effect on some elements of the previously growing sharing economy and other sectors of the economy. At least five points are relevant.

1. Video conferencing has replaced a multitude of workplace interactions with employees increasingly working from home (Lund et al. 2020). A byproduct of this is that many people are moving away from their previous homes in city centers (Patino et al. 2021).
2. The pandemic has stimulated virtual education at all levels ranging from elementary and secondary schools to universities. Also, communications at academic conferences and between businesses have been replaced by remote interactions.
3. The pandemic has promoted “low-touch” and challenged “high-touch” commerce and business. Amazon and other delivery services took on an increasingly important role (Wu 2020). At the same time, “airlines, retail stores and restaurants are among some of the industries heavily [negatively] impacted” (Chang, 2020), and, as a result, many traditional retailers went through bankruptcy (Sozzi, 2020; Wikipedia, 2020b). Generally, although the stock market reached new highs, there was a massive reconfiguration of business activity toward a touchless economy.
4. Other sectors have had to adapt. In particular, many parts of the shared economy faced many challenges, particularly ridesharing. Airbnb, after an initial decline, observed a changing pattern of usage toward people traveling by car to safe homestays (Serwer, 2020). Also, in the real estate sector, commercial real estate owners have received letters from their clients citing force majeure clauses and not paying lease or rent payments. “[W]e are worried about commercial real estate and commercial real estate REIT-structured companies,” said Tim Gilligan, a CFA and financial advisor for Wick Capital Partners in Philadelphia (Chang, 2020). And as for sports, the “Majority of Americans are not ready to go to a sports event, even with masks: poll” (Roberts 2020).
5. Political processes experienced widespread use of video-conferencing capabilities, including the switch to virtual meetings in the 2020 Democratic and Republican Conventions. Some changes may be permanent, such as the nationwide convention roll call-showcasing video from each state (Collinson, 2020). Voting itself became increasingly remote, which stimulated a debate about the potential for voter fraud versus undue restrictions on voting rights (www.cnn.com/2020/08/23/politics/trump-mail-in-voting-gop/index.html).

Before moving to the next topic, it is worth noting that some virtual communities have been developed to fight Covid-19 directly, as, for example, a shared database (Covid-19 Registry of Off-label & New Agents, or CORONA for short) that serves as “central repository of all available data in scientific journals on all the therapies used so far to curb the pandemic” (Prior 2020).

The next section uses the typology as an organizing principle for exploring future applications of virtual communities in various sectors and future research.

Future Applications and Research Topics

The five typology elements described in this chapter – purpose, platform, population, place, and profit model – provide guideposts for directions for the touchless economy in the areas of (1) likely new applications and technologies for medicine, e-commerce, education, and society at large, and (2) future research topics in the social, business, and computing sciences.

Application: medicine Medical care has changed for the pandemic, and these changes will likely be retained after the pandemic has ended. (Pertaining to purpose) Remote doctor visits will be increasingly facilitated by virtual meetings. (Pertaining to place) Some regions or countries may restrict

travel from citizens in high-incidence locales or have particular technology-supported entry requirements, and network applications could help with this. (Pertaining to platform functionalities) Improved sensing systems may facilitate remote medical testing analyzed digitally at home or mailed to laboratories. (Pertaining to population) Some virtual communities may help provide health information and lifestyle guidance for particular target segments including the elderly and people with special needs. (Pertaining to profit and reporting models) Networked medical applications, centralized government record-keeping, and virtual payment systems may help meet reporting requirements for various provincial, state, and federal health services, or for private health maintenance organizations, or to assist with billing logistics for private payments.

Applications: retailing distribution, manufacturing, entertainment, and e-commerce As retailing continues to pivot toward touchless modes of commerce, virtual communities are likely to serve new purposes and functions in a low-touch fashion to replace vulnerable high-touch areas of retailing and distribution. Concerning the *place* element, going out is increasingly being replaced by staying in for meals and entertainment. Thus, restaurants are increasingly emphasizing takeout or delivery. And Netflix was already disrupting more traditional forms of entertainment such as movie theaters before the pandemic, and this trend has only accelerated (Gaus 2020). At the same time, home improvement centers appear to be thriving, as consumers, relegated to their homes, have more time for home-improvement projects. Concerning the *platform* element, retailing and distribution are likely to increasingly employ agents with AI (artificial intelligence), robotics, and immersive environments with various forms of self-service to provide contagion-free contact in such industries as hotels, restaurants, and airline check-in. And concerning profit models, standard retail markups will likely apply, but payments will be increasingly virtual, with touchless checkout in the remaining physical stores using RFID tags on products. And payment

accounts may increasingly shift from cash and credit cards to new monetary forms like WeChat Pay and Alipay (both started in China), or the newly discussed Libra payment system being spearheaded by Apple.

Application: education In less than two months, the world's educational infrastructure, at all levels, took a crash course in offering teaching and learning environments online. Necessity has been the mother of invention, assisted by Zoom and various forms of educational software. Doubtless, the world's teachers, now becoming versed in these technologies, will retain many efficient new practices even after the pandemic. This prompts several questions about teaching pedagogies, accommodations for sports, inculcation of values of professionalism and good citizenship in noncampus settings, conducting exams fairly, willingness to pay for distance (vs. in-person) university education, and top-up health insurance coverage or hazard pay for teachers.

Application: society and government There may likely be a need to adjust government services, such as policies and design standards for public buildings and parks and new legal standards that outline permissible practices for the public and for businesses and new rules and guidance for governance. Of course, sustainable norms of behavior regarding public health are becoming applicable to citizens. But anonymity and the right to privacy will also be issues in the public domain (Warren and Brandeis 1890, Glancy 1979), as a curb to the use of AI systems with such things as facial recognition software.

The design of cities and the architecture of offices and homes are also likely to adjust because people are increasingly working from home, at least some days of the week. Central offices in city centers may not need to be so monolithic, with a more streamlined support staff, socially distanced. Architectural standards will increasingly recognize the need for highly effective ventilation and filtering, and modified use of elevators, adjustments in the structure of large

public spaces, and arrangements of homes that perhaps feature clusters of yards that afford safe small-group communal interaction. Homes themselves may be expected to include more office space in which to conduct remote meetings, possibly free from interruptions by other family members, effective ventilation, ample wireless service, and other support.

Research The five typology elements can also be helpful for organizing past research and for identifying gaps for new research. Table 3 provides a detailed list of research topics organized around the typology described in this entry. (This list builds on a related lists of potential research topics, as relating to virtual worlds, in Messinger et al., 2008a,b, 2009.)

This list raises a host of research and applications issues too lengthy to develop. Briefly, some likely research topics will consider, but certainly not be limited to, new arrangements for work and education, city planning, architecture, and virtual self-presentation, and changing norms of communication. In addition to these issues, other likely topics will include managing virtual communities, themselves; diffusion models of various types of virtual communities in the touchless economy, pairing artificial intelligence (AI) with virtual communities, AI readiness or aversion scales; and whether countries assert impediments to trade, information flow, and access to technology in the virtual realm (Wang & Disis, 2020).

Conclusion

In an Encyclopedia of the Possible, such as this entry, we believe virtual communities constitute a major topic because such communities open up efficient modes of human interaction and societal organization that can help us capitalize on as yet unrealized opportunities and respond to newly realized threats such as the Covid-19 pandemic.

This entry considers a typology for virtual communities consisting of (1) purpose, (2) population, (3) platform, (4) place, and (5) profit model. This typology is helpful for interpreting

how virtual communities make it possible for people to conduct their everyday lives in the touchless economy in a low-exposure-risk fashion. The typology of this entry is also offered to help interpret the future development (including new technological features) and application of virtual communities and to provide guideposts for research about the touchless economy in the social, business, and computing sciences.

One limitation of the typology discussed in this entry is that, as the world changes, other emergent features may become worth incorporating into it. Going forward, one central question concerns the enduring effect of the pandemic. Will all these accelerated changes carry forward after the pandemic or will the world revert the prepandemic era? Will this be true for norms of behavior (mask wearing, social distancing)? Will brick-and-mortar retailing bounce back? Will large-venue entertainment and sports resume? Will people's lives and required patterns of behavior be changed forever, or will we revert back to the golden age of public health of recent generations?

Paulina Paśławska states, "I believe that SARS-CoV-2 pandemic and Global Lockdown will push our digital transformation further and faster than we thought. Standing on the verge of an economic crisis we are highly motivated to transform. This motivation will push us to the next level of digital transformation and automation. 'Touchless economy' won't be the buzzword anymore, it will be the only economy we know" (Shataieva, 2020). A countervailing thought comes from Jacob Morgan, who concludes, "The touchless economy is for convenience, productivity, and efficiency but we must all remember that business still depends on human beings and relationships and that won't change" (Shataieva, 2020).

Overall, the touchless economy has been a needed response to the Covid-19 pandemic. The mainstay of the touchless economy is a mosaic of virtual communities that meet needs that were previously addressed by high-touch activities. The proposed typology of virtual communities helps organize one's thinking about the virtual communities that make up the touchless economy.

Virtual Communities, Table 3 Virtual Worlds (VWs): Open questions and related past work

Typology elements	Open questions for research and application	Some past work
Purpose	How will virtual communities be used after the pandemic? For medicine? For virtual workspaces? For education and distance learning? For running governments, for public consultation, and for elections? To facilitate collaborative design, market research, or test markets? Will virtual meetings in the workplace continue to replace in-person meetings? What are the implications for business? Are there downsides to video-conferencing? Will the downturn in high-touch areas like retailing, sports, large-venue entertainment, and restaurants have a lasting effect? Change: How will delivery of education change? Will growth of the sharing economy change? Which businesses will be the winners (e.g., Zoom and Amazon) and losers? Which brand communities will thrive? Why? Is there a new form of art emerging in the virtual world? What are best practices for managing virtual communities?	Qianqian et al., (2020), Kang et al., (2019), Messinger (2016, 2017), Goh et al., (2016), Driver et al., (2008), Bugeja, (2008), Graves, (2008), DiPaola et al., (2008), Rosenman et al., (2007), Boulos et al., (2007), Bronack et al., (2006), Dickey, (2005), Edwards, (2006), Maher et al., (2005), Nebolsky et al., (2003), Ragusa & Bochenek, (2001), and Roy & Kodkani, (1999)
Population/people	How are people's motivations and behavior patterns different in virtual communities than in physical environments (if at all)? Does increased interaction in virtual communities influence people's self-concept? Will people's attitudes toward self-presentation become more casual or remain the same? Will people use software to improve their appearance real time? How will people choose their virtual backgrounds and for what purpose? What are the demographics, psychographics, geographic characteristics, membership sizes, and participation levels of various virtual communities? What population segments are more or less amenable to using virtual communities? Does this affect media placement for business? Governance and public participation? What role do virtual communities play in elections and political movements (e.g., Black Lives Matter, Arab Spring)? Will growth in specialized information communities (and a possible decline of centrist mass media) lead to societal polarization? Will lack of personal contact have effects on mental health and feelings of alienation, depression, reactance, and backlash as a result of the touchless economy? If so, how should this be addressed?	Le and Duong, (2020), Messinger et al., (2019), Annett and Xu, (2015), Belk, (2013), Barnes, (2007), DMD et al., (2007), Edery, (2006), Hans et al., (2006), Hemp, (2006), Subrahmanyam et al., (2004) and Yee, (2006)
Platform	How can platforms be utilized for virtual service delivery, education, medicine, customer relationship management, electronic retailing, teaching, and libraries? What types of services	Pu et al., (2020), Wang et al., (2020), Yan, (2020), Hendaoui et al., (2008), Kim et al., (2008), Farkas, (2007), Goel & Mousavidin, (2007), Kadavasal et al., (2007), Swanson, (2007),

(continued)

Virtual Communities, Table 3 (continued)

Typology elements	Open questions for research and application	Some past work
	and products will thrive? What platform features will be particularly important and helpful? What pedagogies for teaching and learning will work best virtually? How will this depend on the students' ages and the material? How should the appearance of service agents or instructors be designed? How does the nature of a platform influence people's behavior? Do synchronous and asynchronous forms of interaction differ in meeting people's information needs, stimulating social interaction, or engendering trust? To what extent does lack of anonymity versus desire for privacy influence behavior? Are different platforms more or less conducive to self-governance? Can virtual communities be paired with artificial intelligence for management of the community or delivery of service? Are there measures/scales of AI readiness or aversion?	Hans et al., (2006), Holzwarth et al., (2006) and Sipress, (2006)
Place	Will people continue to increasingly work at home, with fewer in-person days at a workplace? What are the implications for cities and city planning? How will architecture of homes and offices evolve to accommodate increased use of virtual communities? Are the standards and norms of social behavior in virtual communities different from the physical world? Are there specific ethical considerations (e.g., privacy)? Etiquette? Attitudes toward cheating? Sexuality? Should virtual interactions be regulated (as compared to regulation of ISPs)? Will there be country-wide attempts to encourage or control virtual technology and AI? Will laws, regulation, and tax incentives influence creativity and productivity in virtual communities? Do behaviors and attitudes learned in virtual communities affect behaviors and attitudes in the real world? Do virtual communities influence attitudes toward violence, sexuality, and conservatism? What are the crossover effects between virtual e-commerce and traditional retailing and service delivery?	Hwang & Krackhardt, (2020), Wang and Disis, (2020), Messinger et al., (2019), Belk, (2013), Christ & Peele, (2008), Melby, (2008), Adrian, (2007), Cole and Griffiths, (2007a,b), Grabowski & Kruszewska, (2007), Hugues, (2007), Mennecke et al., (2007), Methenitis, (2007), Smyth, (2007), Yee and Bailenson, (2007), Yee et al., (2007), Balkin & Noveck, (2006), Herman, et al., (2006), Mayer-Schoenberger & Crowley, (2006), Nobel, (2006), Ondrejka, (2006), Jansz & Martens, (2005), Whang and Chang, (2004), Anderson and Bushman, (2001), and Sherry, (2001)
Profit model	Will virtual communities support themselves with a single up-front fee, periodic subscription payments, advertising, pay-as-you-go extras, or sales of ancillary products? How important are Freemiums for encouraging membership? Does the payment structure influence whether there is optimal provision of service? How is "optimal" defined? Can the incentive structure reduce the principle-agent problem? Are virtual profits taxable? By which governments?	Xu et al., (2020), Ardley & McIntosh, (2019), Setterstrom & Pearson, (2019), Fang et al., (2019), Li et al., (2019), Bapna et al., (2018), Park et al., (2018), MacInnes, (2006), and Leblebici et al., (1991)

Abstract

We will probably never go to the Moon, climb Mount Everest, or swim with dolphins. Virtual reality (VR), however, can allow us to do all these things using the simulative power of computers and smartphones. Specifically, what distinguishes VR from other media is the sense of *presence*: the feeling of “being there” inside the virtual experience produced by the technology. The feeling of presence, associated with the

high level of emotional engagement allowed by virtual experiences, turns this technology into a powerful tool for exploring what is possible and engaging with it, supporting personal and clinical change.

Keywords

Virtual reality · Presence · Telepresence · Emotional engagement · Personal change · Clinical change · Transformation of flow · Simulation

Definition

Avatar: virtual self-representations used in virtual reality and digital worlds.

Telepresence: the feeling of “being inside” a digital world.

Introduction

We will probably never go to the Moon, climb Mount Everest, or swim with dolphins. Virtual reality (VR), however, can allow us to do all these things using the simulative power of computers and smartphones.

What is VR? The word “virtual reality” is composed by the two words “virtual,” almost or nearly as described, and “reality,” the actual state of things. Consequently, we can state that the term “virtual reality” basically means “almost-reality” or “near-reality,” suggesting that VR is a form of reality simulation.

Computer sciences define VR as a set of fancy technologies used to create a simulated environment (Riva et al. 2015): an interactive 3D visualization system (a computer, a game console, or a smartphone) supported by one or more position trackers and a head-mounted display. The trackers sense the user’s movements and report them to the visualization system which updates the images for display in real time.

However, psychology and neuroscience define VR as (Schultheis and Rizzo 2001) “an advanced form of human-computer interface that allows the

user to interact with and become immersed in a computer-generated environment in a naturalistic fashion” (p. 82). From a cognitive viewpoint, VR is mainly a *subjective experience* that makes the user believe that he/she is there and that the experience is real (Riva et al. 2016). Specifically, what distinguishes VR from other media is the sense of *presence*: the feeling of “being there” inside the virtual experience produced by the technology. In fact, VR has also been described as an *advanced imaginal system*: an experiential form of imagery that is as effective as reality in inducing emotional responses (Vincelli et al. 2001).

In this view, the feeling of presence associated with the high level of emotional engagement allowed by VR (McLay et al. 2012; Rizzo et al. 2010) turns this technology into a powerful tool for exploring what is possible and engaging with it, supporting personal and clinical change (Riva et al. 2016). Specifically, VR helps people become aware of what is possible (an extended field of possibility), engage with what is possible (explore it), by creating digital experiences that test and expand human possibilities.

Virtual Reality and Personal Change

As suggested by psychology (Higginson and Mansell 2008), the process of change requires three critical steps:

1. First, it requires *self-reflectiveness*, an intense focus on the particular instance or experience creating the potential problem (Wolfe 2002). By exploring this experience as thoroughly as possible, the individual can relive and identify all of the significant elements associated with it (i.e., conceptual, emotional, motivational, and behavioral) and make them available for reorganization (Riva 2014).
2. Second, the process of change requires *personal efficacy* (Bandura 2006). Specifically, individuals must believe that they can effect changes through their actions. Without this strong belief, there is no incentive to act or to keep on acting in the face of difficulties.

3. Finally, the process of change can be dramatically boosted by *transformative experiences* (Mezirow 2000), forcing individuals to critically examine and eventually revise their core assumptions and beliefs. Unfortunately, most transformative experiences cannot be planned in advance, but they happen suddenly in individuals' lives, without a prior control on their contents and their effects.

VR is able to effectively support all these steps.

On one side, it provides the individual with a world where he/she can be placed and live a particular experience (Baños et al. 2005). As underlined by Glantz and colleagues:

One reason it is so difficult to get people to update their assumptions is that change often requires a prior step – recognizing the distinction between an assumption and a perception. Until revealed to be fallacious, assumptions constitute the world; they seem like perceptions, and as long as they do, they are resistant to change. (Glantz, Durlach, Barnett, & Aviles, 1997, p. 96)

By using VR, it is possible to develop new, realistic, credible, and informative experiences regarding the surrounding world. This could lead the individual to the realization that what it is assumed to be true is a result of his/her mind (Muratore et al. 2019). More, it allows a precise narrative framing of the experience. As underlined by Balzarotti and Ciceri (2014) positively framed experiences generate less fear than negatively framed ones.

On the other side, using VR, it is possible to develop “virtual adventures” in which subjects experience themselves as competent and efficacious (Riva et al. 2015). Specifically, the VR experience can provide different difficulty levels – from easy tasks to very difficult ones – offering a controlled setting in which the individual is able to develop new skills through trials and errors.

Finally, as recently suggested by Gaggioli (2015), VR also allows the possibility of simulating impossible worlds – environments that do not conform to the fundamental laws of logic and nature. For example, time paradoxes (i.e., the possibility of changing, restructuring the history) and time alterations are impossible manipulation

of physical reality that are instead feasible in virtual reality. We know that to change our world, we have to change our own thinking. In this view, the ability to see the world differently can create significant opportunities that can transform the way we approach the events of our life. In other words, this unique VR's characteristic can be exploited to induce transformative experiences (Chirico et al. 2016) that allow us to see the true threats and true opportunities without the limits of the way we make sense of the world.

These features clearly explain the increasing use of VR in behavioral health and its clinical efficacy. As demonstrated by two recent meta-reviews (Riva et al. 2016, 2019) assessing the meta-analyses, systematic and narrative reviews published in this field, the scientific literature supports the use of VR in the treatment of anxiety disorders, stress-related disorders, obesity and eating disorders, and pain management, showing also the presence of long-term effects that generalize to the real world.

However, another way for explaining VR's transformative potential can be found observing the similarities between the functioning of our brain and the functioning of VR.

Virtual Reality as a Simulative Technology

According to the “predictive coding” theory (Clark 2013; Friston 2010), our brain actively maintains an internal model (simulation) of the body and the space around it, which provides predictions about the expected sensory input and tries to minimize the amount of prediction errors (or surprise). We do not offer here an in-depth discussion of these concepts, because authoritative and thorough accounts have been provided elsewhere (Clark 2013; Friston 2010). However, herein we will focus on the concept of “simulation” introduced by this theory to better understand the links between our brain and virtual reality.

One of the main tenets of predictive coding is that our brain creates an embodied simulation of the body in the world to effectively regulate and

control it (Riva et al. 2019). The main characteristics of this simulation are two: first, it simulates sensory-motor experiences including visceral/autonomic (interoceptive), motor (proprioceptive), and sensory (e.g., visual, auditory) information and, second, the simulations reactivate multimodal neural networks which have produced before the simulated/expected effect.

Virtual reality works in a similar way (Riva et al. 2019). It uses computer technology to create a simulated world that individuals can manipulate and explore as if they were in it. Specifically, VR hardware tracks the motion of the user, while a software adjusts the images on the user's display to reflect the changes produced by the physical motion in the virtual world.

In other words, the VR experience tries to predict (simulate) the sensory consequences of our movements showing us the same scene we will see in the real world. To achieve this, the VR system, like the brain, maintains a model (simulation) of the body and the space around it. The reason why VR simulation tries to get as close as possible to brain simulation is that the more the VR simulation is like the brain model, the more individuals feel present in the VR world (Riva 2018; Riva et al. 2019; Sanchez-Vives and Slater 2005). And this is true also for social interactions with avatars, virtual self-representations in digital world. As demonstrated by Balzarotti and colleagues (Balzarotti et al. 2014), the more VR avatars are recognized as intentional agents, the more users adjust their emotion nonverbal behavior according to the behavior of the avatar.

Virtual Reality as an Embodied Technology

According to the “predictive coding” theory, our brain creates multiple multisensory simulations (Barrett 2017) and not only. Our brains allow the prediction of upcoming sensory events both inside and outside the body, which are also used to predict the best action to deal with the impending sensory events.

However, how are these multiple multisensory simulations handled by our brain? Moseley and

colleagues suggested that these simulations are integrated with real-time perceptive information in the “body matrix,” a coarse supramodal multisensory representation of the body and the space around it (Gallace and Spence 2014a; Moseley et al. 2012; Riva 2018). The mechanism used is the following. First, the contents of the body matrix are defined by top-down predictive signals, integrating the multisensory (motor and visceromotor) simulations of the causes of perceived sensory events (Friston et al. 2010). Then, the different simulations are ranked and included in the body matrix according to their relevance for the intentions of the self (selective attention). Finally, the priority and the content of the different simulations are corrected by bottom-up prediction errors that signal mismatches between actual and predicted real-time perceptive information (Friston 2009).

In this view, the contents of the body matrix are adjusted on the basis of the (dis)agreement (Riva et al. 2018; Talsma 2015) between the perceived sensory activity and the activity predicted through the different simulations which define the satisfaction conditions for the intentions of the individual. This process is bi-directional (Friston et al. 2010), i.e., the body matrix can be changed to accommodate unexpected sensory signals (perceptual inference and learning), and actions are performed to confirm the sensory predictions made by the body matrix according to the intentions of the individual (active inference).

This vision has also two corollaries.

First, this process also allows the body matrix to identify where the self is present, i.e., in the body that is processed by the body matrix as the most likely to be its one (Apps and Tsakiris 2014). Apps and Tsakiris clearly explain:

The mental representation of the physical properties of one's self are, therefore, also probabilistic. That is, one's own body is the one that has the highest probability of being ‘me,’ since other objects are probabilistically less likely to evoke the same sensory inputs. In short, the notion that there is a ‘self’ is the most parsimonious and accurate explanation for sensory inputs. (2014, p. 88)

Second, bodily representations are usually produced and modulated by sensory inputs, but they can exist and produce qualitatively rich bodily

experiences (Melzack 2005) even in the absence of any input signal (e.g., phantom limb syndrome). In this view, the experience of our bodily self can be considered the result of a multimodal simulation. Margaret Wilson stated in this regard that: “The human perceptual system incorporates an emulator. . . that is isomorphic to the human body. . . the emulator draws on body-schematic knowledge derived from the observer’s representation of his own body” (2006, p. 221).

As we have just seen, the sense of presence and the experience of our body (bodily self-consciousness) is the outcome of different embodied simulations. Moreover, VR is a simulation technology. In this view, it is possible to design specific virtual environments (Oliveira et al. 2016; Riva 2018) for altering the experience of the body.

Starting from these premises, in 2007, two European teams of cognitive neuroscientists independently reported in science how VR could be used for altering our bodily experience (producing an out-of-body experience) in healthy volunteers (Ehrsson 2007; Lenggenhager et al. 2007). Since then, the rapid development of immersive VR environments has allowed a new research line due to the possibility of “projecting” (and controlling) the body into external (or virtual) space that is becoming a reality (Costantini 2014; Gallace and Spence 2014b).

But how the experience of “being” in a synthetic body is achieved in these studies? These experiments are an evolution of the trick used in the low-tech rubber hand illusion (Tsakiris and Haggard 2005): the crossmodal congruence between what a person feels via the somatosensory pathways (touch) and what he/she sees in VR. Through this approach different authors used VR to induce an illusory perception of a fake limb (Slater et al. 2009) or a fake hand (Perez-Marcos et al. 2009) as part of our own body and to produce an out-of-body experience (Lenggenhager et al. 2007), by altering the normal association between touch and its visual correlate. It is even possible to generate a body transfer illusion (Slater et al. 2009). Slater and colleagues substituted the experience of male subjects’ own bodies with a life-sized virtual human female body. Interestingly, altering the experience of the

body has significant effects also on social cognition, for example, the experience of ownership over an a body of different race results in significant reductions of the levels of implicit bias against that race (Maister et al. 2015).

These studies suggest that VR can be defined as an “embodied technology” for its possibility of modifying the bodily experience (embodiment) of its users (Riva 2016, 2018; Riva et al. 2019). In general, it is possible to modify our bodily self-consciousness in three different ways (Riva 2016; Riva et al. 2012; Riva and Mantovani 2014; Waterworth and Waterworth 2014):

- *By replacing the contents of bodily self-consciousness with synthetic ones (Synthetic Embodiment):* As we have seen before, VR allows different type of synthetic bodily experiences. The most advanced is the “full body swapping” in which the individual’s body is substituted by a virtual body (Petkova and Ehrsson 2008). In other words, as in the movie *Being John Malkovich*, by using VR individuals can experience the perspective of another individual, seeing what the other sees, hearing what the other hears and touching what the other touches.
- *By structuring bodily self-consciousness through the focus and reorganization of its contents (Mindful Embodiment):* Individuals have different levels of body awareness, is the extent of sensitivity and attentiveness to bodily signals and sensations (Ginzburg et al. 2014). VR can be applied for improving body awareness when it is integrated with other technologies like biosensors. For example, in integration with biofeedback training, it can be used to assess and control specific body signals like heart rate, galvanic skin response, electromyography or electroencephalography (Gaggioli et al. 2014; Repetto et al. 2009) that are normally not consciously perceivable, and to report these back to the patient. The patient can then learn to shift these measured signals in the desired direction by means of the feedback provided by VR (i.e., a waterfall changes its flow according to the heart rate of the individual).

- *By augmenting bodily self-consciousness to achieve enhanced and extended experiences by altering/extending its boundaries (Augmented Embodiment):* By integrating VR with biosensors, stimulation and haptic devices, it is possible to map the contents of a sensory channel to a different one – e.g., vision to touch or to hearing – in order to increase its sensibility and replacing the impaired channels (Waterworth and Waterworth 2014). For example, Ward and Meijer (2010) virtual sound experience to convert information normally delivered to the visual field into an auditory representation. As noted by the authors, “The users both report detailed visual phenomenology that developed within months of immersive use and has continued to evolve over a period of years” (p. 492).

Virtual Reality as a Transformative Technology

Up to now VR has been used to simulate external reality in order to make people feel “real” something that is actually not really there (i.e., in the environment). However, the ability of VR to fool the predictive coding mechanisms that regulate the experience of the body also allows it to make people feel “real” what they know isn’t real. In other words, VR can offer new ways for structuring, augmenting, and/or replacing the experience of the body for clinical goals (Riva 2008, 2016; Riva et al. 2017).

Specifically, it is possible to use the simulative potential of VR for exploiting/enhancing (transformation of flow) and/or for correcting (embodied medicine) the embodied simulations used by the brain to drive perception, action, and emotions.

As underlined by positive psychology (Delle Fave et al. 2011), to cope with dramatic changes in daily life and to access new environmental opportunities for action, individuals may develop a strategy defined as transformation of flow (Riva et al. 2006): the ability of the subject to use an optimal experience for identifying and exploiting new and unexpected resources and sources of involvement. A specific optimal experience that is connected to transformation of flow is “awe”

(Bai et al. 2017; Guan et al. 2018). In fact, awe consists of two central features (Bai et al. 2017; Guan et al. 2018) which are needed for accommodation and perception of vastness; both of these can induce a significant reorganization of the predictive/simulative mechanisms of the brain:

- *Accommodation:* an update of the predictive coding to accommodate unexpected experiences (Bai et al. 2017; Guan et al. 2018).
- *Perception of vastness:* an update of the predictive coding to diminish the individual self, facilitating the integration into social collectives (Bai et al. 2017; Guan et al. 2018).

A clearer picture of the complex relationship among awe and brain activity was recently provided by a voxel-based morphometry (VBM) study. As demonstrated by Guan and colleagues (Guan et al. 2018), awe involves multiple brain regions associated with cognitive conflict control, attention, conscious self-regulation, and socio-emotional regulation, suggesting its potential role in adjusting/improving their functioning. Moreover, different studies demonstrated (Chirico et al. 2016, 2017; Quesnel and Riecke 2018) that both immersive videos and interactive VR can induce awe. In this view, VR inducing awe experiences may be used to induce “transformation of flow” (Gaggioli et al. 2013): a broad empowerment process within the flow experience induced by a high sense of presence. The proposed approach is the following: first, identify a possible experience that contains functional real-world demands; second, use VR to produce the experience and induce awe; and, third, allow the cultivation, by linking the awe experience to the actual experience of the subject (Riva et al. 2018). Different studies are providing a first support to the feasibility of this approach (Gaggioli et al. 2017).

Another approach, based on a similar rationale, consists in using VR to correct a dysfunction of the predictive coding mechanisms (Di Lernia et al. 2018a; Riva et al. 2017). Different authors (Riva 2018; Riva et al. 2017) recently suggested that an altered functioning of the predictive and simulative mechanisms of the brain might be the cause of different neurological and psychiatric conditions.

Therefore, it should be possible to compensate these deficits by using VR to modulate and/or integrate/replace the different contents of the body matrix (Riva 2018). Specifically, VR can be used to generate new crossmodal associations between bodily stimuli (e.g., for a male, being in a female body) that have not been experienced as systematically related before (Chen and Spence 2017). Moreover, the crossmodal association has to produce a *significant prediction error* (high surprise), reducing the level of estimation uncertainty, to update the predictive internal models of the body matrix through the generation of new priors (Riva et al. 2017). Using this approach, technology can be used:

1. *To facilitate the integration of external and inner body signals* (Azevedo et al. 2017; Suzuki et al. 2013).
2. *To induce a controlled mismatch between the predicted/dysfunctional content and the actual sensory input* (Serino et al. 2016).

The emerging fields of interoceptive feedback (Suzuki et al. 2013), sonoception – i.e., the use of sound and vibration to modify inner body signals (Azevedo et al. 2017; Riva et al. 2017) – and body illusion techniques (Costantini 2014), support the feasibility of this approach. For example, Di Lernia and colleagues developed an interoceptive stimulator that is both able to assess interoceptive time perception in clinical patients (Di Lernia et al. 2018b) and to enhance heart rate variability (the short-term vagally mediated component – rMSSD) through the modulation of the subjects' parasympathetic system (Di Lernia et al. 2018a). The integration of these technologies with VR in a multisensory simulative platform will allow the modulation of both the external and internal bodily information, to structure, augment, and/or replace the contents of our bodily self-consciousness (Riva et al. 2019).

Summary

Virtual reality (VR) is a new form of human-computer interface allowing the user to interact

naturalistically with and become immersed in a computer-generated environment. To change our world, we have to change our own thinking. In this view, the ability of VR of showing us possible worlds, sometimes radically different from our actual experiences, can create significant opportunities that can transform the way we approach the events of our life. In other words, this unique VR's characteristic can be exploited to induce transformative experiences that allow us to see the true threats and true opportunities without the limits of the way we make sense of the world. Specifically, VR helps people become aware of what is possible (an extended field of possibility), engage with what is possible (explore it), by creating digital experiences that test and expand human possibilities.

Conclusions

Probably we will never use a space rocket. However, virtual reality (VR) can easily allow us to experience it using the simulative power of computers and smartphones.

The term “virtual reality” is composed by the two words “virtual” – almost or nearly as described – and “reality,” suggesting that VR is a form of reality simulation.

This is achieved using a set of fancy technologies (Riva et al. 2015): an interactive 3D visualization system (a computer, a game console, or a smartphone) supported by one or more position trackers and a head-mounted display.

However, VR is also a new form of human-computer interface allowing the user to interact naturalistically with and become immersed in a computer-generated environment (Schultheis and Rizzo 2001).

We know that to change our world, we have to change our own thinking. In this view, the ability of VR of showing us possible worlds, sometimes radically different from our actual experiences, can create significant opportunities that can transform the way we approach the events of our life. In other words, this unique VR's characteristic can be exploited to induce transformative experiences (Chirico et al. 2016) that allow us to see the true

threats and true opportunities without the limits of the way we make sense of the world. Specifically, VR helps people become aware of what is possible (an extended field of possibility), engage with what is possible (explore it), by creating digital experiences that test and expand human possibilities.

In conclusion, even if VR had been already used in behavioral health obtaining effective results, the exploitation of the link between core brain process and the simulative potential of VR may be the core of a new transdisciplinary research field which uses VR to improve (transformation of flow) and correct (embodied medicine) the embodied simulations produced by the brain.

“What If” Thinking

Nicholas Rescher

Department of Philosophy, University of
Pittsburgh, Pittsburgh, PA, USA

Abstract

“What if?” is the doorway of speculative thinking. For as it matures, the human mind is not limited to factualities alone and truths and falsities are not the only objects of its consideration. We are the only objects of its consideration. We are in a position to consider situations we neither accept nor reject but simply regard as instructive possibilities. From the cognitive point of view we are amphibious creators, with minds that can adapt (be it correctly or not) the realm of the real but can also function in the realm of mere supposition.

Keywords

Assumptions · Conditionals · Hypotheses ·
Paradox · Suppositions

As it matures, the human mind is not limited to factualities alone and truths and falsities are not

the only objects of its consideration. We are the only objects of its consideration. We are in a position to consider situations we neither accept nor reject but simply regard as instructive possibilities. From the cognitive point of view, we are amphibious creators, with minds that can adapt (be it correctly or not) the realm of the real but can also function in the realm of mere supposition.

The speculative wonderment of “What if?” paves the way to the imperatively conditional: “If-then.” For the proper response to what-if questions is generally of the format if-then. (Question: “What if he misses the train?” Answer: “If he misses the train, he’ll miss the boat.”) And what makes such an answer correct is the linkage between its antecedent and its consequent, be it empirical and contingent as in the train/boat example or logico-acceptability necessary. (Question: “What if one of the five people present leaves?” Answer: “If one of the five people present leaves, then only four people will remain.”) Thus in answering a “what if” question by a response of the format “If - - then . . .,” we are looking to the consequences of that dash-indicated antecedent.

“What if” is the hallmark of supposition and of hypothetical reasoning. Such suppositions are matters of factual pretense, of cognitive play-acting: they state not actual facts but mere assumptions and hypothesis. Unlike assertions and postulations, the do not affirm what is or is taken to be so, but only what is taken provision-

ally and pro tem – not for purposes of affirmation and information but only for purposes of consideration and exploration. The response to "what if?" questions differ from "since-because" claims in that they suspend belief in the antecedent. Here the critical thing is mere supposition, a proceeding that dispenses with belief.

"What-if" thinking provides a vastly *versatile* instrument. In scientific context it is a guide to experimentation ("What if we X and Y at a high temperature?"), in everyday contexts a goal to planning ("What if a misfortune X were to occur, how could we protect ourselves against its consequences"); or it could be an instrument of criminal investigation ("If X committed a crime, what clues and indications might yet remain to show this?").

A key issue to address here is that of the semantical condition and status of the conditional antecedent. It must, of course, be *meaningful* otherwise we don't know what we are about. But it lies in the very nature of end hypotheticals that it need certainly not be *true*. Nor even need it even be something that is *possible*. There is virtually no limit to supposition. Beyond meaningfulness, assumptions are subject to no further restrictions. Not even logical self-consistency is required here, seeing that *ad absurdum* reasoning provides a clear counter-example.

As such, supposition is a resource of virtually unlimited scope. One can make suppositions about virtually anything – not just matters of conceivable fact, but also questions, injunctions, instructions, actions, problems. However, we shall here focus on fact-purporting suppositions on the order of: "Suppose that . . . were so, then - - ." And the affirmation at issue in the antecedent need not be an accepted truth. Its truth-status may be either false or unknown and problematic.

"What if" hypothesizing is a functional proceeding: meaningful supposition and assumption is a proceeding made for a purpose and many possibilities are at issue here:

- *Consequences-exploration*. Answering questions of the format: What would have to be the case if we stipulated that - - -. This in turn leads to two others.

- *Indirect proof* and *ad absurdum refutation*. Establishing that some thesis must be the case because the assumption of its negation would entail a contradiction or a vitiating infinite regress.
- *Dialectical refutation*. Indicting that some contention should be rejected (abandoned) because of untenable consequences.
- *Dialectical circumstances*. Indicted that some contention should be accepted because otherwise some acceptable facts would remain un- or under-explained. And this in turn Encompasses the following:
- *Thought experimentation* for versions of elucidation or exploration (especially in context of scientific understanding).

The sole cogent basis for rejecting inherently meaningful assumptions as illicit and inappropriate roots in their functionality: the nature of the supposition must not conflict with its purpose. For example, nothing is wrong with assumptions recognized and acknowledged as false – unless the purposed context is one of fact-explanation. Inherently meaningful assumptions face of further impediment then of factual suitability.

"What if" questions are notably common in historical speculations. A plausible example of this is the counterfactual:

If Wellington had lost at Waterloo, then Napoleon would not have been forced into (immediate) exile in St. Helena.

This admits of the following justificatory analysis:

Accepted facts:

- (1) Wellington did not lose at Waterloo
- (2) Wellington and Napoleon were opposed commanders at Waterloo
- (3) Napoleon went into (immediate) exile
- (4) Victorious commanders are not forced into immediate exile.

Assumption: not-(1): Wellington lost at Waterloo

In attempting to resolve consistency in such cases, the issue-formative assumptions are of course sacred. But even if we drop (1) in the

wake of the assumption, we still have a contradiction. For this assumption together with (2) entails "Napoleon won at Waterloo," so that "Napoleon was a victorious commander." And this together with (4) yields not-(3).

Given that (2) is not an issue here, our assumption of not-(1) in effect forces a choice between (3) and (4). And when we prioritize general relationships over particular facts – as is standard in counterfactual situations – we will retain (4) so that (3) must be sacrificed. And on this basis that initial counterfactual becomes validated.

Yet another plausible example of an informative historical counterfactual runs as follows:

If Julius Caesar had not crossed the Rubicon in revolt against the Roman republic, this republic would have endured far longer.

Here we have:

Accepted facts:

- (1) Caesar crossed the Rubicon in revolt against the Roman republic.
- (2) Caesar's revolt destabilized the republic and rendered it unstable and untenable.
- (3) Without this modality and conditionality the republic would have endured far longer.

Assume not-(1). Then by (2) Caesar's actions has not (would not have) rendered the republic unstable and untenable so that by (3) it would have endured longer. Here the conditional at issue follows simply from the hypothesis plus the limited register of salient facts.

As such illustrations indicate, restoring consistency in the case of counterfactuals envisions a priority ranking – a "prevailing order" of retainability that governs the process of breaking the chain of inconsistency at its weakest link. It is geared to the principle of fostering informativeness via the sequential prioritization of:

- issue-definitive hypotheses, suppositions, and assumptions
- definitive concept-conceptions and meaning-correlative relationships
- generalizations, "laws," well-established general rules, well-confirmed causal and factual relationships

- established trends, common relations among events, connections among particular eventuations
- specific, particular, contingent facts and concrete eventuations

Thus the priority situation in these *speculative* cases is exactly the reverse of the order of evidential security that obtains in the factual setting of *inductive* reasonings, where theory must give way to facts and more far-reaching theories to those that are more particular in their bearing. And in this regard specifically historical counterfactuals are in the same boat as others in that they pivot on considerations of rational economy via a Principle of the Conservation of Information that insists on optimizing our understanding of things in the face of incongruities.

Even patently false suppositions can thus be tenable in matters of counterfactual reasoning. Consider a simple example. We take ourselves to know that:

- (1) Bizet was French.
- (2) Verdi was Italian.
- (3) Compatriots belong to the same country. And now against this background let us make the supposition.
- (4) [Assume that] Bizet and Verdi were compatriots.

Obviously we now have a logical inconsistency on our hands. What to do? In the very logic of things, something has to give way: the chain of inconsistency must be broken. But where, when, and how?

To restore consistency we must clearly abandon one of (1)–(2). The other premisses are safe. In arising at this position the following priorities are in place:

- Thesis (4) is secure as the postulated assumption at issue.
- Thesis (3) is secure as a terminological definition.
- Thesis (3), albeit accepted truths, have comparatively lower priority than the preceding.

Accordingly one of (1) or (2) must be abandoned, but both have exactly the same claims to retention, we are led to the conditional:

If Bizet had Verdi had been compatriots, then either Bizet would have been Italian or Verdi would have been French.

As this example shows, a cogent line of reasoning leading to a clearly acceptable conclusion can result for a patently false and combination-generating supposition. By explanatory principles of cognitive damage control, instructive and informative cognitive work can be accomplished under the auspices of "what if" reasoning.

As this example illustrates, the task of rational deliberations and inquiry is to extract the maximal amount of useful information from the data at our disposal – to answer the questions we have in the most extensive yet reliable way that is possible.

A crucial difference is operative when new data are introduced by way of discovery (finding and observation) and by way of supposition (hypothesis and assumption). For in the former case if the data don't fit, it is they themselves that will need readjustment. But assumptions are sacrosanct. Other, preexisting materials have to be revised to make places for them. Reciprocal adjustments is the instrument of consistency in mandating either way. An optimal landscape of reciprocal accommodation has to be achieved one way or another. But the rational economy of its realization is accomplished on an agent.

Paradox analysis affords another illustration of this phenomenon.

Suppose we adopt the underlying principle at issue in the classic "Paradox of the Heap":

- If n sand-grains do not constitute a heap, neither do $n + 1$.

And in the wake of this supposition we are confronted with two further concepts:

One or two sand-grains do not constitute a heap.
A million sand-grans constitute a big heap.

It is clear that the sequential addition of sand-grains will engender a contradiction here, seeing that we realize full well that eventually a heap is

before us. So we arrive at the puzzle: "What if to a single grain of sand we keep adding more. Just when do we arrive as a heap?"

As noted above, the priority order of claims on retention in the face of counterfactual supposition runs as follows: (1) the assumptions and suppositions whose postulations are at issue, (2) definitions and terminological explanations, (3) general laws, rules, and principles, (4) speculative contingent factualities, and (5) plausibilities and probabilities. Such a hierarchy of epistemic-tenacity status obtains and serves to determine the weakest link at which to break the cycle of inconsistency that confactual suppositions engender.

And so, in the wake of these considerations we have no alternative but to reject that seemingly plausible addition principle in the face of more fundamental factualities. But of course the question "At just what point is the transition from non-heaps to heaps made?" is one that has no answer; it is inappropriate on grounds of resting as on mistaken presupposition. Transition there is and must be, but it is not punctiform. In this regard the question is based on the erroneous presuppositions of potential exactitude.

One useful and very common use of thought experimentation relates to its *explanatory* employment. We here reason along the lines of "If only such-and-such were the case, then something-or-other (which otherwise would be very difficult to explain) now admits of a ready and satisfying explanation." For example, Thales (sixth century B.C.), the very first of the nature philosophers of ancient Greece, proposed to explain the annual flooding of the Nile as the result of a backing up of its outflow due to the opposing force of the annually recurrent Etesian winds.

Overall, a proper thought experiment involves five stages overall: supposition, context specification, commitment adjustment, conclusion deriving, and lesson drawing. And at each of these stages a mishap or malfunction can in theory arise.

- The supposition can turn out to be meaningless.
- The context may be set up inappropriately, in relation to the purposes of the thought

experiment in particular by way of error of omission.

- The commitment adjustment may fail to be realistic, in particular by way of errors of omission that plunge matters into inconsistency.
- The course of reasoning by which the intended conclusion is drawn may be flawed and erroneous.
- The wrong lesson can be drawn for the experiment by overlooking possibilities for its interpretation.

In sum, all sorts of procedural flaws can in theory arise to vitiate a thought experiment.

Given that real experiments belong to the natural sciences, philosophers are greatly drawn to thought experiments. And so they are drawn to strange and eccentric hypotheses – suppositions on the order of brain transplants, communicating rocks, or intelligent amoebae.

However, philosophy's interests being largely theoretical and abstract, the standards of precision, generality, exactness, and the like that are used by philosophers have traditionally been far higher than those of the practical people concerned with everyday affairs. Accordingly, philosophers have generally looked upon language as imperfect and inadequate – in need of tidying up, clarification, and supplementation (if not outright replacement). But everyday concepts do not admit of this improvement without revision – and thus without abandonment. They are made for everyday use in real-world situations and cannot survive unaltered in the more stressful theoretical atmosphere of strongly hypothetical concerns. In projecting wildly fanciful hypotheses, philosophers bent on theoretical tidiness often end up annihilating the very concepts they are to clarify. Some conceptions are – like that of a "heap" – simply unable to survive the misguided attempt to instill them with exactness.

When thought experiments are projected in the context of ethical deliberations regarding personal behavior or social practices, one has to be mindful that the ethical norms of conduct are instrumentalities designed for use in the conditions and circumstances of this world's general and ordinary

course of things. The rules and regulations of ethics and morality are everyday guidelines designed to function in everyday circumstances and conditions. Accordingly, hypotheses that project extreme and altogether extra-ordinary conditions will not be relevantly serviceable for the task in hand. And this is not just because suppositions that contemplate considerations of extreme scarcity (e.g., killing one healthy individual to use his organs and body parts for saving many) are too outlandish and far-fetched for contemplation but because the course of their development has designed our ethical concepts and principles with very different sorts of situations in view. These far-fetched hypotheses in that specific deliberative setting are inappropriate and will be unable to meet the cognitive needs of the situation.

Like most any other tool or mechanism, if-then thinking is a productive resource brought into being for the realization of purposive aims. And all such resources are functionally limited. Instrumentalities and applications have to harmonize: one cannot sew with a hammer nor anneal with a needle. And if-then thinking, however useful in many contexts, cannot transcend the limits of meaningful application. Reasoning is by definition limited to the confines of rationality and cannot by its nature produce instructive information from nonsense. "If angels are dancing on the head of a pin, then how many of them could fit?" is a question which, if not exactly a meaningless is nevertheless a pointless one.

All in all, then, thought experimentation is open to various sorts of error. Thought experiments can err by relying on background information that is misinformation. They can involve errors of reasoning to arrive at conclusions that do not actually follow from the premisses at hand. They can address questions that rest on flawed presuppositions. Exactly because they are suppositions projected with a view to answering questions and resolving problems. Just this is why thought experiments can fail – just as real experiments can. They can do so by failing cogently to provide an answer to the question they are designed to resolve. Or else

they can provide the right answer to the wrong question.

Abstract

Wisdom has been a central theme in the philosophical inquiry of the human experience for centuries, with the earliest written teachings dating back to the ancient Egyptian vizier, Ptahhotep 25-24 century BCE. The virtue of wisdom has been attributed to the great deities of various cultures and mythologies (e.g., Anahit of Armenia, Athena of Greece), and a quality humankind is encouraged to embody millennia later. In more recent decades, psychological scientists have begun to study the concept of wisdom, exploring characteristics of a wise person as well as meta-cognitive processes and moral aspirations involved in wise decision-making. At the core of wisdom is the recognition and acceptance that for any given issue there are different possible perspectives, interests, contexts, and outcomes, as well as the willingness to consider and take into account these different possibilities when working through the issue. This chapter reviews the psychological study of wisdom, with a focus on the conceptual and empirical construct of wisdom as it relates to *the possible*.

Keywords

Wisdom · Wise reasoning · Metacognition · Moral aspirations

Defining Wisdom

Greek philosophers viewed wisdom as a way of understanding the world (Durant 1961). To philosophers like Plato and Aristotle, wisdom was one of the most fundamental human virtues, a means of contemplating truth and guiding human conduct (Adler 1952). Though this perspective dominated Western philosophy for hundreds of years (Birren and Svensson 2005), the conceptualization of wisdom evolved throughout history, leading to numerous and culturally diverse definitions of wisdom (Kung and Grossmann 2020). This presented a challenge to its empirical study, because while the plurality provided rich roots for empirical investigation, it also created conceptual ambiguity among researchers regarding the components that comprise such a complex psychological construct, with different researchers prioritizing different philosophical accounts in their conceptualization of wisdom (Grossmann et al. 2020b).

In lay terms, wisdom has many definitions, ranging from knowledge drawn from traumatic life experiences and personal growth, to intelligence, and rationality (Staudinger and Glück 2011). Within psychology, some scholars have studied wisdom from a person-centric perspective (e.g., Ardelt 2003), while others have argued that wisdom can vary based on context (e.g., Grossmann et al. 2016; Grossmann et al. 2020a; Staudinger and Baltes 1996). Early psychological studies took a person-centric conceptualization of wisdom, where wisdom was characterized as a stable trait that an individual possessed (Birren and Svensson 2005). According to this account, people portray consistent and stable levels of wisdom across time and situations (e.g., “a wise or unwise person”; Webster 2007). In other words, wisdom is a trait that one either possesses or does not possess, reducing the notion of wisdom to (often) immutable characteristics of an individual. Recent empirical investigations take a broader approach. Although there is a moderate stability in people’s tendency to deploy wisdom in reasoning (e.g., metacognitive processes that lead to wisdom), there are also considerable within-

individual differences in how much people use wise reasoning, which varies according to context (Brienza et al. 2018; Grossmann et al. 2016, 2019a). Thus, the degree to which a person engages in wise reasoning can differ across time and situations, with certain contexts facilitating wisdom while other situations constrain it. For example, recent work has found that people use more wise reasoning when they are around others (Grossmann et al. 2016), when they take others’ perspectives (Kross and Grossmann 2012), or in relationships they care more about (Rotella and Grossmann in preparation).

To overcome the operationalization heterogeneity of wisdom in the social sciences (Staudinger and Glück 2011), leading scholars in this area of research established a common wisdom model (CWM), which includes moral, social, and cognitive approaches to wisdom, and provides a clear and overarching conceptualization of wisdom as a psychological construct (Grossmann et al. 2020b). The CWM is especially useful to understand wisdom from a social-sciences perspective. According to this model, wisdom is defined as “morally-grounded excellence in social-cognitive processing,” highlighting two elements which are most characteristic to the construct: *metacognition* and *moral aspirations* (Grossmann et al. 2020b). Metacognition refers to higher-order thinking; in other words, thinking about and regulating one’s thought-processes, cognitions, emotions, and motives (Dunlosky and Metcalfe 2008). In the context of wisdom, metacognitive processes allow people to step back from a situation (e.g., the problem they are considering at the moment) to assess, evaluate, and adapt their approach, taking into consideration things like “*what is my goal?*”, “*is the current approach working?*”, and “*what are the consequences of this approach?*” (Grossmann et al. 2020b). Though not an exclusive list, the CWM encompasses the following metacognitions as central to wise reasoning: (1) context-adaptability; (2) epistemic humility; (3) integration of diverse viewpoints; and (4) perspectivism. Context-adaptability involves recognizing that contexts can change, and maintaining an open mind about

such possible changes. It could present as searching for different solutions as a situation evolves, or considering alternative possible ways in which a situation could unfold (Grossmann 2017; Grossmann and Dorfman 2019). Epistemic humility involves recognizing the limits of one's knowledge. This can manifest as questioning whether one's existing opinion on an issue is correct, recognizing that one may be lacking relevant information, and actively searching for extraordinary circumstances prior to forming an opinion. Integration of diverse viewpoints involves searching for a compromise between competing perspectives and interests. This process can include identifying possible compromises, or searching for a solution that would bridge competing interests. Lastly, perspectivism involves maintaining an open mind toward the possibility that there are different viewpoints concerning a given situation. It could manifest as making an active effort to take others' perspectives, or seeking a variety of opinions on a matter prior to arriving at a conclusion.

The second foundation of the common wisdom model concerns moral aspirations, implying that wisdom meta-cognitions have to be morally grounded. The notion that these metacognitive processes are morally grounded means that wisdom guides individuals to make decisions that promote the common good and well-being of others (Grossmann 2017, 2020). The moral component of wisdom encompasses balancing self- and other-oriented interests, the pursuit of truth (vs. dishonesty), and an orientation toward shared humanity (i.e., recognizing we all share a common human experience regardless of group memberships; Grossmann et al. 2020b). Importantly, according to the CWM, wisdom-related metacognitive processes and moral aspirations work as a unit; these metacognitions *without* moral aspirations would be more descriptive of a sociopath than a wise person (Grossmann 2020; Sternberg 1998), as the fundamental reasoning processes of a sociopath would be focused on the self in isolation of others, rather than considering how one's actions are integrated into a broader context. Relatedly, moral aspirations without metacognition would simply be abstract

concepts that would be difficult to implement. For example, to effectively pursue the truth, one would need to engage in perspectivism (e.g., maintaining an open mind about different possible viewpoints) and intellectual humility (e.g., acknowledging the limits of their own knowledge).

Notably, wisdom as conceptualized by the CWM is not fully explained by other conceptually related constructs (Grossmann et al. 2020b). Wisdom is not merely intelligence: in examining the relationship between intelligence (IQ) and wisdom, scholars suggest that while a certain level of IQ is necessary for wisdom, in that it facilitates cognitive processes, it is not sufficient to achieve wisdom. Moreover, IQ does not consistently predict the moral aspects of wisdom and only weakly predicts performance on tasks assessing the various features of wisdom (e.g., Grossmann et al. 2020b). Wisdom is also distinct from rationality, with empirical work showing that wisdom and rationality share only a weak relation (Brienza et al. 2018). And though some scholars have suggested that wisdom and emotional intelligence (i.e., the ability to perceive, understand, express, manage, and use emotions; Mayer and Salovey 1997) are conceptually the same (Zacher et al. 2013), both lay perceptions of wisdom and wisdom scholars tend to contradict this suggestion (Grossmann et al. 2020b). In a study evaluating short statements associated with wisdom, participants perceived that wise people are equally capable of problem-solving and reasoning as intelligent people; however, wise people also had sagacity – which are interpersonal skills associated with knowing when to listen to others, having flexibility in interactions and relationships, and balancing long- and short-term consequences (Sternberg 1985). Moreover, in a recent survey among experts of the Wisdom Task Force which explore this idea, none of the experts viewed emotional intelligence alone as a sufficient factor for wisdom. That is not to say that emotional intelligence is unrelated to wisdom. In fact, many experts view emotional intelligence as a prerequisite for wisdom; however, they argue that these are two distinct constructs (Grossmann et al. 2020b). Similarly, most wisdom experts

identified perspective-taking (i.e., “the capacity to recognize and coordinate the differences in people’s perspectives,” Baltes and Staudinger 2000) to be a necessary component of wisdom, but not sufficient on its own to capture the entire wisdom construct (Grossmann et al. 2020b).

Wisdom and the Possible

Although wisdom is desirable across many contexts, it is particularly relevant in social relationships and social conflicts (Grossmann et al. 2020a; Grossmann and Dorfman 2019). While relationships are an integral part of the human experience, maintaining them requires effort. Interpersonal conflicts can arise, calling for one or both parties to keep an open mind, consider different possible solutions, and reach a compromise that maximizes both parties’ interests. In other words, one would need wisdom to effectively sustain relationships. Consider the following scenario:

A person at the department where I work is angry at me over something that isn’t my fault. It is actually another person’s fault for not communicating information with them. I feel stuck in the middle and like no one will take responsibility. I just tried to defend myself when the angry person came in and talked about the situation. I explained that the head supervisor had told me that they wanted to communicate with this person. I promised to avoid miscommunications in the future. I feel annoyed and attacked because it’s not my responsibility to play their office politics games.

Many of us can relate to a conflict similar to the one highlighted above. How might one deal with such a situation? Recall that wisdom involves taking others’ perspectives, placing a problem into a broader context, realizing the limits of one’s knowledge, and integrating these ideas (Grossmann 2017; 2020). By engaging in these metacognitive processes, people *interact with the possible* – that is, they deliberate about alternate possibilities, which would have otherwise been constrained without using wise reasoning processes. A person dealing with the above situation could entertain the possible by double-checking if their formed opinion of what occurred is in fact

correct. For example, is it true that this “other person” did not communicate the pertinent information? Are there extraordinary circumstances that could explain why this information was not passed on to the appropriate people? One might also consider taking the perspective of the others involved, prior to forming a conclusion about the given event. In a conflict such as this, wisdom would allow one to approach the situation with a focus on the “big picture” (Grossmann and Dorfman 2019; Grossmann et al. 2016), instead of concentrating on little details that could misconstrue the event or misjudge those involved. Deploying wisdom-related meta-cognitive considerations in such a conflict would facilitate the consideration of a variety of possibilities in terms of understanding what occurred and how the situation might further unfold.

In fact, wise reasoning has been related to many constructs that facilitate engagement with the possible. Wise reasoning has a moderate positive relationship to crystallized intelligence (e.g., Grossmann et al. 2013; Staudinger et al. 1997, 1998) which can allow people to relate current experiences to more accumulated knowledge, facts, and skills. Wisdom has also been related to personality constructs, where people who used more wisdom were also more open to experience, agreeable, and less neurotic (Brienza et al. 2018; Huynh et al. 2017; Kunzmann and Baltes 2003; Levenson et al. 2005; Mickler and Staudinger 2008; Webster et al. 2014). People who are more open to experience, have a larger active imagination, greater aesthetic sensitivity, are more attentive to feelings, have a preference for variety, and have greater intellectual curiosity (Costa and McCrae 1992), all of which are characteristics that allow people to engage in more experiences and possibilities. Agreeableness is a personality construct associated with being kind, sympathetic, cooperative, warm, and considerate (Costa and McCrae 1992), which also facilitates perspective taking and integrating perspectives – two wise characteristics that enable cognitive engagement with alternate possibilities. On the flipside, people who score high on neuroticism have greater anxiety, worry, fear, anger, frustration, envy, and loneliness, and are more likely to

interpret ordinary situations as threatening (Costa and McCrae 1992). These characteristics constrain engagement with alternative possibilities, and instead are associated with less cognitive flexibility (Murdock et al. 2013). Likewise, wise reasoning is associated with greater emotional diversity, emotional regulation (Grossmann et al. 2019a, b; Grossmann et al. 2016), and interest and inspiration (Kunzmann and Baltes 2003). Thus, wise reasoning is associated with cognitive and personality characteristics that enhance engagement with the possible.

Wisdom further facilitates engagement with the possible for large-scale and important social issues (Grossmann and Brienza 2018; Sternberg 1998). In recent years, we have seen the devastating consequences of climate change, observed terrorism in various parts of the world, and lived through a global pandemic. Circumstances such as these require us to deliberate on what is possible, in both considering how a situation may unfold and ways of resolving it. Wisdom facilitates this. For example, during a pandemic, nations would benefit from wise leadership (Grossmann and Dorfman 2019). This could look like national leaders maintaining an open mind of how the trend of positive cases may evolve throughout the year and searching for different solutions accordingly (context-adaptability). In fact, leadership learning has been associated with greater wisdom (Yang 2014). This could also include maintaining an open mind about the various viewpoints offered by experts in different fields (e.g., health, economics) and integrating these prior to making any decisions (perspectivism). Here, wise leadership could also manifest as acknowledging that one does not have all the answers and could be lacking relevant information (epistemic humility). As well, it could entail searching for a solution that maximizes the number of interests satisfied (e.g., for students, elders, business owners; integration of diverse viewpoints). As established previously, wisdom is rooted in morality; as such, wise leadership during a global pandemic could look like recognizing that all humans share a common fate regardless of their country of residence and thus collaborate internationally to discover a vaccine

(shared humanity). Wisdom in this context would enable leaders to consider the different possible ways in which the pandemic could evolve and the possible ways in which it would be best addressed.

In addition to identifying and considering different perspectives and possibilities, wisdom is also concerned with balance and integration. This component of wisdom is necessary to avoid infinite deliberation on possible alternatives. Integration of alternatives becomes particularly relevant in situations in which one must decide how to act. To illustrate this point, consider the ongoing COVID-19 pandemic. Government officials and their consultants do not have an infinite amount of time or resources to consider *all* of the ways in which it could unfold and develop mitigation strategies in accordance with each and every possibility. A delay in decision-making can have catastrophic consequences (e.g., thousands of preventable deaths). Faced with multiple alternatives in such a situation requires consideration of how to balance and integrate them.

Fostering Wisdom

Using wise reasoning has many benefits. Wisdom is associated with greater life satisfaction, greater longevity, less negative emotions, less depressive reflection, and can promote prosociality (Grossmann et al. 2013, 2017). Thus, to facilitate engagement with alternate possibilities, perspectives, and contexts – that is, to consider the possible – we must first understand how to facilitate and promote the use of wise reasoning.

Recent research suggests that self-distancing by taking a third person's perspective – i.e., considering a conflict as a distanced or uninvolved observer – facilitates wisdom (Dorfman et al. 2020; Kross and Ayduk 2011; Kross and Grossmann 2012). In a series of studies, Grossmann and Kross (2014) examined the role of self-distancing on wise reasoning. Participants were randomly assigned to reflect on a situation in which their partner cheated on them, or their best friend's partner cheated on their friend, and to reason about how the relationship would unfold

moving forward. They found that participants assigned to the “other” condition (i.e., thinking about their friend’s relationship) scored higher on wise reasoning, confirming that self-distancing from a situation can facilitate greater wisdom. In a follow-up study, an infidelity situation was presented once more. This time, participants were assigned to one of four condition, instructing them to either: (a) consider this to be their own problem from an immersed perspective (self-immersed), (b) consider this to be a friend’s problem from an immersed perspective (other-immersed), (c) consider this to be their own problem from a distanced perspective (self-distanced), or (d) consider this to be a friend’s problem from a distanced perspective (other-distanced). Self-distancing was manipulated via the use of first-person or third-person pronouns when reflecting on the conflict (e.g., “I am feeling. . .” vs. “She/he is feeling. . .”). The authors found that participants in the other-immersed and other-distanced conditions engaged in greater wise reasoning than those in the self-immersed condition. Further, participants in the *self-distanced* condition portrayed greater levels of wise reasoning than those in the self-immersed condition. Notably, those assigned to the other-distanced and other-immersed conditions did not differ from those assigned to the self-distanced condition in their wise reasoning, demonstrating that distancing of any manner (i.e., other-immersed, other-distanced, self-distanced), promotes similar levels of wise reasoning. In a third study, the researchers explored whether age plays a role in wisdom. Contrary to the popular belief that “with age comes wisdom,” they found no age differences in wise reasoning among younger or older adults, and further, that the self-distancing intervention worked equally effectively for both age groups. These findings confirm that no matter one’s age, taking the perspective of a distanced observer can inspire greater wise metacognitions, allowing one to explore the possible. This is consistent with similar research, such that perspective taking enhances creativity, and in turn, exploring what is possible (Glăveanu 2020).

Additionally, engaging in future-oriented perspectives can increase wise thinking. For

example, reframing how someone reflects on a situation (i.e., “*how would I feel about this in the future*” vs. “*how do I feel about this now*”) can help people approach conflicts more wisely (Huynh et al. 2016; Kross and Grossmann 2012; Robson 2019). Further, in the context of relationship conflict, creating temporal space between the self and situation can promote greater insight, greater forgiveness, and greater relationship well-being, while reducing partner blame and negative emotions about the relationship (Huynh et al. 2016).

Another effective method of self-distancing is the use of third-person language (i.e., “*What should she/he do about this?*” vs. “*What should I do about this?*”). Engaging in ego-decentering has shown to increase wise reasoning in hypothetical scenarios (Grossmann and Kross 2014; Kross and Grossmann 2012) and in autobiographical real-life experiences (Grossmann et al. 2019b). The use of third-person language was recently examined as a means to prospectively facilitate wisdom. In a recent micro-longitudinal study, participants wrote a daily diary entry over a 1-month span; they were instructed to record their reflections of a noteworthy daily experience using a first- or third-person perspective (Grossmann et al. *in press*). The researchers found significant increase in wise metacognitions in participants’ reflections on a recent personal social conflict after (vs. before) the third-person reflections intervention, a promising sign that one could implement a specific technique such as journaling using third-person language to promote wise reasoning when dealing with a new conflict. These findings suggest that reframing how someone thinks about a situation, problem, or conflict can promote greater wisdom and the exploration of various possibilities.

Conclusion

We have discussed the conceptualization of wisdom, highlighting that the metacognitions encompassed by the common wisdom model (i.e., context-adaptability, perspectivism, epistemic humility, and integration of diverse viewpoints) are

morally grounded, guiding individuals to make decisions that promote a common good. Importantly, we established that at the very core of wisdom is the recognition and acceptance of the possible, and reviewed empirical findings of how wisdom is associated with greater possibilities. Whether it is the consideration of different perspectives, viewpoints, interests, solutions, or outcomes when reflecting on a given situation, wisdom allows us to explore the possible.

Abstract

This entry proposes a sociocultural approach to wishes and wish-making, distinct from existing psychoanalytical and cognitive discussions of this phenomenon. It considers wish-making as part and parcel of everyday life and one of the main ways we have to engage with the future and attempt to construct it according to our needs and desires. Wishes are not signs of intrinsic irrationality, nor markers of pathological functioning; instead,

they are embedded in human action and connect us to the possible, to others, and to the world. The entry starts by reviewing research into different types of wishes before considering in more detail theories and studies of wish-fulfilment and wishful thinking. It concludes with a reinterpretation of wishes as having their own scope, rationality, and as being intrinsically related to the ethical.

Keywords

Wish · Wish fulfilment · Wishful-thinking · Sociocultural psychology · Possibility

Synonyms

Desire; Wishful thinking

Wishes and wish-making are fundamental parts of a human type of existence, capturing something essential about our connection to the world not only as is, but as we would like it to be. Through the act of wishing, we express a human desire to make the world more hospitable, more appealing, to (re)organize it in ways that help us grow and flourish. Everyday language is filled with expressions related to wish-making and wish-fulfilment, including “do as you wish,” “having a wish list,” “your wish is my command,” “wishing someone well,” or “careful what you wish for.” The last one points to the fact that there is always a gap and a point of tension between the wish as imagined and formulated and the wish as real or enacted. The latter has sometimes more unexpected and far-reaching consequences than the former. The wisdom needed to choose one’s wishes well is a common theme in stories, from the legends of Greek and Roman antiquity (e.g., the myth of Pygmalion) to medieval and more modern tales (e.g., the story of Snow White or the tale of Aladdin). Wishing on a shooting star, when blowing the candles on a birthday cake, or tossing a coin into a fountain are all small, everyday gestures related to wish-making.

This is how, today, we have in different fields of psychological science a rich vocabulary related

to wishes, one that includes the interconnected notions of need, drive, impulse, instinct, resistance, motive, and so on (Ghent 2002). And yet, lay uses of the term are often overextended, making “I wish” become almost synonymous with “I want.” As such, different authors have been eager to note that wishes are not intentions (Heckhausen and Kuhl 1985), desires (Wellman and Woolley 1990), hopes (Miceli and Castelfranchi 2010) or, indeed, needs (Ghent 2002). This lack of clarity made especially those researchers following the behaviorist tradition determined to either specify wishes better (Watson 1916) or to replace altogether this notion (e.g., with “demand”; Seeman and Buck 1952). Even those working within the psychoanalytic orientation, whose conceptual system is premised partially on wishes and related concepts, expressed at times frustration with the term, proposing, for instance, to use instead the wider notion of “motivational systems” (Ghent 2002). These systems prepare the organism to adaptively respond to either appetitive or aversive stimulation, determining the course of learning (see Lang and Bradley 2010).

The difficulty in defining what a wish is comes partially from a series of misconceptions regarding their nature, in particular, the supposed dichotomies between wishes and reality, on the one hand, and wishes and reason, on the other. Wishful thinking, a topic that will be reviewed later on in this entry, is commonly assumed to distance us from reality, biasing our perceptions and leading us to potential errors in judgement. As George Orwell (1945) famously noted on the topic, people can foresee the future only when it coincides with their own wishes. But this doesn’t mean that wishes are actively disconnecting us from reality – on the contrary, they “grow” out of it and respond to it, being at all times in a close interplay (Babad et al. 1992). Related to this first misconception is the often-implicit idea that wishes are driven by emotion and, as such, frequently irrational. For example, the topic of infantile wishes and fantasy are widely studied within psychoanalysis (Eagle 1990), including the relation between wish-making and magical thinking (Vikan and Clausen 1993). All of these ultimately bring the topic of wishes close to that of pathology and pathological

functioning rather than “normal,” adaptive, and mundane acts.

This entry will strongly argue for the latter and against the former by proposing a sociocultural (rather than psychoanalytical) account of wishes. This account starts from the basic observation that wish-making is part and parcel of everyday life and one of the main ways we have to engage with the future and attempt to construct it according to our needs and desires. This is not an irrational or pathological type of activity, even when (as we will see), wishful thinking can indeed bias our perceptions and, at times, lead to deception or failure. Wishes dwell in the space between motives, emotions, and the imagination, as well as that between self and others. Indeed, as I will argue towards the end, while wish-making opens up a new horizon of possibility in our lives, this horizon is very much influenced by societal norms, cultural conventions, and power relations. In other words, what is experienced as a highly personal act of wish-making is, at once, a psychological and sociocultural activity. Wishes, I argue, are not as general as desires or needs and yet not as specific as intentions or goals. By occupying this “in-between” space, they both orient our thinking about a possible future and allow it to be flexible and, thus, to build futures rather than singular visions of what could or should be. Last but not least, wished futures tend to be more or less likely, sometimes very close to what is achievable, other times explicitly impossible (Miceli and Castelfranchi 2010). Either way, wish-making remains motivating for the person, infused by affect and forged within the (inter)actions that make up our social and cultural existence.

The entry starts with a brief review of types of wishes that are commonly studied in psychology and related disciplines, before discussing wish-fulfilment as the cornerstone of the psychoanalytic approach to dreams, motivation, and the functioning of the psychic. Wishful thinking is addressed next, an area of research informed much more by cognitive and neuroscience theories and methods and, therefore, “biased” towards discovering errors and biases in our (wishful) engagement with the world. I end by arguing that the latter should be considered as much

more than a sign of biased or irrational thinking and, drawing on Aristotle, show that wish-making is a social and ethical form of anticipating the future.

Wish Research

Over the past decades, there has been increasing research into wishes and wish-making, underpinned by various conceptual frameworks and covering a wider range of processes and domains. In this section, I will review three main areas studied by “wish researchers,” namely, development and the life course, mental-health, and society. It is important to note from the start, though, that oftentimes the notion of wish is used as a synonym for desire, need, or intention, and, as such, many of the papers reviewed below lack a proper reflection on the nature and functions of wishes beyond specific cases.

When it comes to human development, a variety of wishes are assumed to play an important part in our lives from birth to old age. As I briefly mentioned above, infantile wishes are an area of study in its own right, one we will return to in our next section. For the moment, we can focus on other wishes that have developmental effects, for example, the wishful identification of young children and teenagers with different role models. Konijn, Nije Bijvank, and Bushman (2007) considered the “darker” sides of these processes when they chose to study wishes and identification in relation to violent video games and their consequences for aggression in adolescent boys. Unsurprisingly, this study showed that subsequent acts of aggression were more intense for the boys who not only played violent games but wished to become like the characters they played. And this when game exposure, trait aggressiveness, and sensations seeking were controlled for. Remaining within the same general stage of development, Parker, Thoemmes, Duineveld, and Salmela-Aro (2015) studied the psychological and academic outcomes of wishing (or not) to take a gap year (i.e., a year of break or exploration between the end of school and university enrolment). Existing theories and research point, in this

context, to both positive and negative consequences of this practice. The study referred to, conducted in two different contexts (Finland and Australia), showed no differences between students who wished and didn't wish to take such a year in terms of a variety of outcomes (e.g., goal commitment, effort, expectations of attainment and strain, actual university enrolment, career prospects, life satisfaction). But it did interestingly show that gap-year students were more likely to drop out of a university degree.

Moving to the adult age, considerable research has focused, for some decades, on the wish for a child. For instance, Jeker, Micioni, Ruspa, Zeeb, and Campana (1988) examined this wish and its relation to infertility in the case of 116 couples. Starting from the assumption that infertile parents may present emotional conflicts when it comes to wishing to have a child, the authors carried out psychodynamic interviews and found, indeed, severe conflicts especially in female participants with no clinically defined organic infertility factors (a relationship less evident in their male partners). Another population under investigation is represented by undergraduate students who are feminists and their wish for a child. Gerson (1984) found, in this regard, that feminism was negatively related to the motivation for motherhood and made salient mostly the costs rather than benefits of parenthood. Of course, such results need to be placed in context, in view of society's changing conceptions of gender roles. Finally, another "adult" wish under investigations is that of continuing to work or stopping work, again in view of changing conceptions about the meaning of working. Harpaz (2002) found, in the Israeli context, that the vast majority of people expressed a wish to continue working even if they won a big lottery prize and that key factors in wishing not to work anymore were, among others, a strong instrumental orientation, low work centrality, organizational obligation, and low occupational satisfaction.

Finally, in old age what has been mostly investigated are wishes to move (especially their abandonment in forced immobility) and the wish to die. The former, explored in a research by Coulter (2013), showed that the risk of abandoning the

wish to move raises considerably with age, "suggesting that the well-documented residential rootedness of older people is not solely volitional" (p. 1944). In addition, it is not only age but ethnicity and income level that are strongly linked to fulfilling a moving wish. The wish to die or suicidal ideation is unfortunately common in people who get to a very old age. Barnow and Linden (2002) studied this phenomenon in a German sample and found co-occurrence with major depression or other psychiatric disorders, high age, being a woman, and negative life conditions (e.g., living in a nursing home and being unable to move out).

These studies connect well to the second main area of research – mental health. In this field, Tiggemann, Gardiner, and Slater (2000) explored the wish to be thinner in adolescent girls and concluded, based on focus groups, that sociocultural influences, especially the media, exert the strongest pressures to be thin. But, importantly, young girls also show an unexpected level of sophistication in how they understand the role of the media on body image and self-views. In other words, wishing to be thinner doesn't necessarily mean being dissatisfied with one's body, at least upon further reflection. Related to the above, dieting wishes have been researched by Johannessen, Oettingen, and Mayer (2012), who showed that mentally contrasting this wish with present reality and constraints promotes a commitment to feasible goals, while mentally indulging in a desired future does not (i.e., in the former condition, participants reported having eaten fewer calories overall and fewer high-calorie foods, as well as being more physically active). Thus, the need to account for present obstacles in order to better define our wishes and increase their chance of fulfilment.

Other mental health concerns relate to the wish to be held and the wish to die. The first one, studied by Stein and Sanfilipo (1985), is especially present in people with high levels of depression and in women. However, it is to be noted that both sexes reported such wishes but, if for women this wish is an invariant across levels of depression, only males who described themselves as more depressed (than other males) expressed

feelings of dependency and, as a consequence, a more intense wish to be held. Finally, the wish to live and to die has been mainly studied in cases of suicide. Brown, Steer, Henriques, and Beck (2005) discussed these two wishes as engaging in an internal struggle whose outcomes have a determining effect when it comes to suicidal behavior. And yet, having such an internal struggle relates already to lower suicidal intent scores than a unidirectional drive towards death alone (see Kovacs and Beck 1977), showing the importance of a heterogeneous motivational stance.

Last but not least, most research on wish-making and society relates to votes, politics, and the prediction of election outcomes (a topic we will return to in the section on wishful thinking). To give just one example, Babad and Yacobos (1993) focused on wishful thinking in Israeli voters in the 1988 election and showed substantial effects of this phenomenon. Ultimately, predictions of election outcomes as well as the interpretation of events depended greatly on political wishes and preferences. At the same time, political allegiance did nuance the intensity of wishful thinking, suggesting again that community and identity variables play a role in what and how we wish for, including in politics. And this holds also for those wishes that go counter to expectation. For instance, Leshem (2017) studied the wish for peace in an intractable conflict like the Israeli-Palestinian one. Focusing only on the Jewish-Israeli side, he found that, while hopes for peace are low but found across different definitions of peace, wishes for peace are more dynamic, higher and, for right-wingers, dependent on what kind of peace was proposed (the most concrete definition, the less right-wingers wished for it). Wishes, ultimately, are both shaped by and continuously shape one's political orientation.

Wish-Fulfilment

The topic of wish-fulfilment deserves its own separate section given, on the one hand, its old historical roots (arguably it marks some of the first scientific studies of wishes) and, on the other, the distinct theoretical underpinning of these studies.

If the research referred to above draws on multiple conceptual frameworks, from clinical and individual differences to social and political, wish-fulfilment is firmly grounded in psychoanalytic or psychodynamic thinking. This field has its origin in Freud's famous study of dreams and his assumptions that dreams – one of the “royal” ways to our unconscious – are a form of wish-fulfilment. In his words, “the content of the dream is thus the fulfilment of a wish; its motive is a wish” (Freud 1900, p. 20). According to Freud, this is easier to recognize in the case of some dreams that directly respond to a wish we remember when aware, and more difficult for others, especially anxiety-dreams. And yet, the latter are some of the most fruitful ones for a psychoanalyst given that “there is always the possibility that even our painful and terrifying dreams may, upon interpretation, prove to be wish-fulfilments” (p. 33). As such, a painful or terrifying dream, instead of invalidating the hypothesis of wish-fulfilment, makes us wonder even more as to what kind of wish is being met by feeling sad or frightened. “Wherever a wish-fulfilment is unrecognisable and disguised there must be present a tendency to defend oneself against this wish, and in consequence of this defence the wish is unable to express itself save in a distorted form” (p. 37). In fact, for Freud, dreams play two main roles. Because of the hallucinatory fulfilment of oftentimes unconscious wishes, they provide our psychic a “safety valve,” discharging instinctual energies. And, because they also preserve our desire to sleep by transforming sleep disturbing stimuli, dreams are equally the guardians of sleep.

Freud intuited from 1900 that children's dreams, often simpler, give the best examples of wish-fulfilment, an assumption that received empirical support more than a century later in studies such as the one performed by Colace (2013). He traced not only the frequency and types of wish-fulfilment in the dreams of young children but also the daytime experiences these dreams most probably referred to. The findings clearly show that children's dreams most often fulfil a recent, daytime wish, especially when associated with an intense affective state. In fact,

dreams seemed to resolve the tense affective state, something that Colace formulated as the “affective-reestablishment hypothesis.” Combining psychoanalytic insight with neuroscience research pointed to greater activity during dreaming in areas of the brain involved in the reactivation of affective components and memories. As such, dreams and the wishes embedded within them dissipate the emotional charge accumulated during daytime and reduce next-day subjective emotionality. According to Colace:

Through the elaboration of daytime affective experience, the dream allows the child to obtain emotional restoration and to continue sleeping undisturbed. In other words, wish-fulfillment dreams resolve an affective state and provide ‘affective reestablishment.’ In accordance with this interpretation, we note that the children often appeared calm and serene while reporting these wish-fulfillment dreams. (p. 167)

Just to note before the end that wish-fulfilment research doesn’t only relate to dreams or draw on Freudian notions. There is another strand of studies that considers the actual fulfilment of wishes and its role, especially the wishes of children with life-threatening illnesses who are made true by parents or charities (see Ewing 2009; Darlington et al. 2013; Galinsky 2014). These studies point to an interesting set of findings, for example, the fact that the fulfilment of a special wish might provide the child with a sense of the future and can ease suffering and sorrow both for the child and the family (especially when receiving support by professionals, given that the wish also signifies the seriousness of the illness). Overall, these studies indicate the importance of empathy and of nurturing dreams and hopes in those who suffer. But is such wishful kind of thinking always positive?

Wishful Thinking

Wishful thinking is perhaps the topic that has been studied most extensively, at least within the cognitive tradition. In simple terms, it designates “a desirability effect as the inflation of the judged probability of desirable events or the diminution of the judged probability of undesirable events”

(Bar-Hillel and Budescu 1995, p. 71). Even more briefly, it is “people’s tendency to believe what they wish to be true” (Trope et al. 1997, p. 105). Different authors tried to specify this concept further, by distinguishing it from motivated reasoning (Krizan and Windschitl 2009) and self-deception (Szabados 1973). When it comes to being overly optimistic, Vosgerau (2010) clarifies that wishful thinking refers to overoptimism about future events that are unrelated to the person’s performance (in contrast to what we call overconfidence). In any case, it is widely assumed that wishful thinking encompasses a broad range of phenomena and that, while it participates in some forms of pathology, it is certainly not limited to the mentally ill (Trope et al. 1997). In fact, for some, all thinking is wishful thinking (Kruglanski et al. 2020), by which they mean that all thinking is motivated, while others see it as more restricted in scope, arguing that people can be both overly optimistic and pessimistic about the future (Vosgerau 2010).

One of the typical assumptions of a cognitive approach to wishes and wishful thinking is that they can easily bias us, inclining individuals to wrongly estimate the likelihood of a desired future, i.e., overestimate the probability of favorable outcomes and underestimate the one of unfavorable outcomes. In this way, an association is made between wishful thinking and irrationality or, at the very least, the assumption is raised that wish-making can distort reality. However, not everyone supports this view; for instance, Neuman, Rafferty, and Griffiths (2014) make the point that, actually wishful thinking can help us sometimes make better decisions, especially when we have limited cognitive resources to evaluate the future. Through simulations of decision-making processes, they demonstrate how including a bias towards wishful thinking can lead to better performance across a range of decision-making environments. This is because, in fact, calculating the probabilities of everything that is possible is computationally intractable and wishful thinking compensates for this. Such an outcome, of course, depends on time and resource

constraints. “As the horizon that the agent can consider increases, the gain for an optimistic policy decreases, and optimism eventually becomes detrimental to performance” (p. 1214). Overall, though, instead of an error, wishful thinking seems more to be an adaptive strategy we all use, at least once in a while.

How does this “strategy” develop? Vikan and Clausen (1993), based on previous research, assumed that children between the ages of 4 and 6 believe that people can be controlled either by wishful thinking or magic, on the one hand, and more realistic means (like rewards and punishments) on the other. What they found in their study is that magical behavior was considered more efficient than wishing, and that emotion could influence more than thinking. This is, once more, seen as a bias leading to inaccurate conclusions. For instance, it is known that preschoolers typically overestimate their own performance across a wide range of tasks. Schneider (1998) showed that, actually, overpredictions are rather due to wishful thinking than poor metacognition, and that they were more frequent for unfamiliar compared to familiar tasks. Research on adults is even wider in scope. Gordon, Franklin, and Beck (2005), for example, demonstrated a relation between wishful thinking and memory in that people have a bias to attribute desirable predictions to reliable sources and undesirable ones to unreliable sources. Also, that wishful thinking effects depend on retrieval processes and that wishes concerning one event can produce a source memory error for others. Similar effects have been found in social research, for instance, where the likelihood of in-group members to be better in a competition is judged higher than the likelihood of competitors (Price 2000). Finally, there is as well some neuroscience research into wishful thinking, “locating” it in the activity comprising parts of the left inferior occipital and fusiform gyri cluster with functional connectivities of this cluster with the human reward system (Aue et al. 2012). This MRI study asked participants to predict the likelihood of their favorite and least favorite team winning a football game.

In terms of domains, wishful thinking has been documented in a variety of fields, oftentimes with problematic effects. Seybert and Bloomfield (2009) documented wishful betting in financial markets, within a laboratory setting. They also showed that market interaction increases rather than decrease wishful thinking, leading often to contagion. Babad and Katz (1991) had already evidenced that favorable outcomes are considered more likely for preferred teams, for example, in soccer stadiums and at betting stations (see also Babad 1987). Moreover, explicit instructions to be objective did not reduce wishful thinking, fans often betting emotionally and against their financial interest. Elections have also been researched in view of the same phenomenon, and findings here show that, indeed, there is a strong link between preference (wish) and expectation (prediction) (see Uhlener and Grofman 1986; Babad et al. 1992; Babad 1997; Krizan et al. 2010). Once more, this was often maintained even when the instruction to be as objective as possible was formulated and when financial rewards were promised for an accurate prediction. More mundane phenomena, such as procrastination, seem to be related to wishful thinking as well. Wishful thinkers procrastinated when expecting an unpleasant, but not a pleasant task, while low wishful thinkers did not procrastinate (Sigall et al. 2000).

Wishes and Possibility

Regardless of the fact that psychoanalytic and cognitive approaches are highly distinct from each other, they do seem to converge when it comes to specific assumptions about wishes and wish-making. In both literatures, wish fulfilment and wishful thinking seem to be driven by irrational rather than rational forces. However, while psychoanalysis sees wish fulfilment, including through dreams, as part of “normal” functioning, cognitivists are by and large inclined to consider wishful thinking a bias that leads to inaccuracies and errors.

The sociocultural account proposed at the start rejects both the irrationality of wish-making and its relation to errors. While it might well be the case that, in specific contexts, wishful thinking doesn't help us predict outcomes realistically, this doesn't mean that its function is to mislead us. Instead of dichotomizing our understanding of wishes along the lines of reality – fantasy, normality – pathology, and accuracy – error, it would be more useful to return to the core of what wishes “accomplish,” which is to relate us to the future and to the possible. And this engagement is never reduced to thinking processes or emotional reactions alone. It is part and parcel of our actions in and on the world, and the outcomes we envision for such actions. Aristotle, in his *Nicomachean Ethics*, addressed this issue when he related human action to choice, deliberation, and wish (see Mele 1984). For him, the origin of action is choice and choice, in turn, depends on desire (wish) and on reasoning with a view to an end (deliberation). While choice and deliberation received considerable attention in commentaries on Aristotelian ethics, wishing has not. Mele (1984) considers this a serious shortcoming, given that wishes relate to autonomy, a property that is essential for any theory of human action. Even more important, for Aristotle, wishing was related to rationality and goodness given that “we wish only for that we think to be good” and that “wish is the only form of desire found in the rational part of the soul” (pp. 139–140). This is clearly distinct from what psychoanalysts and especially cognitivists made of wishes and wish-makers. It is because wishes are desires which the person identifies that they reflect, at least in part, the kind of person he or she would like to be. In this way, for Aristotle, wish-making is a form of action that involves the ethical as it directs us to possible futures we construct as good.

A direct link to possibility was also made by Miceli and Castelfranchi (2010) in their discussion of hope and wish. For the two authors, hope includes a “belief of possibility about an event p , together with a goal or wish that p occurs”

(p. 255); in other words, wishes are an integral part of hoping and, in some ways, reduced to an expectation. As we have discussed before, however, wishes are much more than goals – they are orientations towards the future that is, at once, open and imagined as hospitable or favorable. Hope and wish can co-occur in building this kind of imagination, but they can also remain separate. Miceli and Castelfranchi interestingly brought in the notion of uncertainty to qualify hope, uncertainty both about the positive outcome and one's self-efficacy in bringing it about. The fact that imagined futures are never fully under our control has a big part to play in wish-making as well, where uncertainty might in fact increase rather than decrease the intensity of one's wish. This is not “illogical” wishful thinking, but a fundamentally human act of dwelling within the future and the possible. “As soon as some wish arises in our mind, the sea of possibilities comes to the forefront, together with a sea of consequent hopes” (p. 259).

In the end, it is important to note as well that, according to the sociocultural approach, society and its institutions also play a determining role in what we wish and hope for. From an early age, fairy tales shape our imagination of what is possible, allowed, and what kind of wishes can find fulfilment (Rikxin and White 1913). Play and games further specify the universe of what is possible to think about and to wish for. The “sea of possibilities” mentioned just above is for some people and in some circumstances, extremely narrow, even inexistent. And yet, the possibility of wishing things to be different is always present. Even when we don't exactly have the means and resources to fully understand what this different future might involve, we can still wish for change. This is the “hidden” energy behind most social movements and forms of activism, and it is also a valuable source of transformation for the self, within everyday life. Wishes might not always come true but the act of wishing, in and of itself, reflects the power to envision the world differently than it is. And this capacity is essential for our existence as agentic, social, and ethical beings.

Centre for the Science of Learning and
Technology, University of Bergen, Bergen,
Norway

Abstract

Wonder is a mundane experience and, at the same time, a transformational state of mind in which we more or less suddenly become aware of an expanded field of possibility and start exploring it without the expectation of reaching a particular outcome or understanding. Wondering helps us dwell into the unknown as a goal in and of itself. This entry starts from a brief history of thinking about wonder before moving on to a conceptual model of it and, finally, reflecting on the practical implications of wondering in education, work, and in society. The history of this phenomenon brings to the fore our changing relationship, through the centuries, with emotions, knowledge, and certainty. The theoretical framework proposed connects wonder to the possible and postulates the inter-related processes of being aware of, excited about, and exploring new possibilities. In this way, wonder includes both a passive, receptive, and an active or dynamic dimension balancing wondering at and wondering about. Final reflections are offered on the importance of wonder for the person and for society.

Keywords

Wonder · Creativity · Imagination · Awareness of the possible · Excitement about the possible · Exploration of the possible · Education · Work · Society

Wondering is a mundane type of experience. Children wonder about why adults behave the way they do and what might be expected of them. Students ask themselves questions about an astonishing fact they learnt at school. Managers reflect on what the future might hold for their workers and for the company. Politicians ponder the meaning of the latest polls. Scientists are surprised by a particular finding and what it says about current theories. Historians are excited to discover a document that sheds a completely new light on ages we thought we know all about. Young people wonder why grownups are not doing more for the climate when so many communities suffer around the globe. For millennia, priests and other religious figures pray to understand the will of God and its mysterious ways. From antiquity until today, we all look up the night sky and marvel at the stars, looking for an answer to life's big questions: Why are we here?, What is the meaning of our existence?, and What exactly happens when it ends?

All the examples above illustrate moments of wonder or, rather, events, questions, and contexts that can trigger wondering. This does not mean we always get to wonder about the behavior of other people, the future, our planet, or the meaning of life. Not every question we raise or ask ourselves comes out of a place of wonder and not all reflection is synonymous with being in this state (for an interesting distinction between the two, see Gasché 2006). This is where everyday language can be misleading. We commonly say that we “wonder” when we simply “think” about things. The commonality between thinking and wondering has to do with the fact that, in both cases, we strive to know or to understand something. But while thinking, driven by curiosity, looks for an answer, wondering paradoxically does not. Or, rather, it opens us up to multiple answers and, above all, the possibility that none of them are correct, that there is much more that we still do not understand and we should continue to think about.

In this sense, wonder is both mundane in terms of the things that can prompt it and rare in terms of the specific processes that differentiate it from curiosity, contemplation, or pondering about

things. This entry will start with a brief history of our conceptions of wonder and our waxing and waning interest in it (for other accounts of this history, see Daston and Park 1998; Llyod 2018). Then it will briefly outline a conceptual model of wonder by identifying what is specific for this phenomenon vis a vis related experiences and examining three interrelated processes that make up wonder. Importantly for this encyclopedia, this conceptualization of wondering relates it to the possible and depicts it as one of the main ways of becoming aware of an expanded field of possibility and exploring it without the need for immediate closure or for finding the one, correct answer. When we wonder, we experience not knowing not as a precursor to knowledge, but as a generative state in its own right. And what this generates, first and foremost, is a sense of the possible.

A Potted History

Both the experience of wonder and our need to make sense of it are arguably as old as our species. From the moment our ancestors could use signs and tools to take some distance from the here and now of their existence and became able, with the help of cultural means, to reflect on this existence, wondering was not far behind. In fact, given the close relation between wonder and the experience of not knowing, we can hypothesize that wondering came before epistemic certainty. Prehistoric people must have marveled at nature and tried to understand its workings. As they did, their curiosity was kindled and then satisfied, leaving room for more curiosity to emerge. But some questions could never be fully answered, and they continued to fascinate, startle, and even frighten us. The first evidence of wondering comes, of course, from antiquity when recorded history gives us a clearer glimpse into the minds of our ancestors. Ancient Greeks, for example, knew how to appreciate this strange state of mind that seeks knowledge without ever being fully content with it. Socrates made this experience the cornerstone of gaining wisdom about self, others, and world. Philosophy is born

out of wonder – a remark that echoed through the ages (Plato 1903).

But wonder and wondering have not always been revered. On the contrary, seventeenth-century philosophers seriously doubted the value of these phenomena. Considering wonder an emotion, Descartes (1989) feared that it can easily cloud judgement. As the “first passion,” admiration opens us up to the world, but it can also confuse us, especially if it is not guided by reason. Too much wondering can make the wondered perplexed and unable to think or act. This is an old theme that, once more, takes us back to Socrates and to his death. Socrates had famously been condemned by Athenians to death by poisoning for the crime of corrupting the mind of the young. This meant that, instead of dealing with the practicalities of life and being active and decisive citizens, young people following Socrates indulged in meditating about life and, most of all, came with more questions out of it rather than answers. Socrates’ crime was, thus, cultivating wonder. Descartes was not keen on understanding what we do not know and might never know; he famously wanted to know what knowledge he could trust. *Cogito ergo sum* – I think therefore I am – leaves little place for further doubt, at least about this basic principle.

Fast forward to the twentieth century and we are witnessing a rediscovery of wonder in the work of Martin Heidegger (1994). Heidegger was inspired by ancient Greeks and, key among them, Socrates, when he revalued wondering as the mission of any philosopher. Dwelling into the unknown is once more seen as a worthwhile experience and not the opposite of reason or action. In order to grasp the world at a phenomenological level, we have to doubt all our assumptions and relinquish the taken for granted. And Heidegger did produce philosophical work that is still appreciated today because of its wonder-triggering qualities. But his legacy was also made problematic by the fact that, while wondering about experience in general, he failed to take note of or react to the horrors of the Nazi regime. Was this wonderment, as the ancient judges of Socrates would say, disconnecting him from the world? Was it clouding his reason, Descartes would ask?

Hannah Arendt (1978) reflected precisely on this kind of questions and came to a different conclusion – the true value of wonder is to make us better, more aware and more critically engaged citizens. When we wonder we question, and this is what totalitarian regimes across history fear the most.

The history of wondering about wonder is thus one of controversy and of moving between dichotomies: knowing and not knowing, emotion and reason, action and nonaction, as well as certainty and the unknown. Predictably, the appreciation of wonder grew in those ages in which certainties were actively questioned and a more comprehensive view of reason, in its relation to emotion, prevailed. What about today?

Twenty-first-century accounts of wonder are characterized by an attempt to use scientific methods to examine the exact nature of this experience. Neuroscience studies of wonder, as well as awe, are often complemented by a more phenomenological approach, closer to the one adopted by Heidegger himself (for an example, see Gallagher et al. 2015). At the same time, there is a growing interest in wonder from a social science and humanities perspective. My own concern for this phenomenon stems from the study of creativity and, more recently, of human possibility. If wonder is the generative state thinkers like Socrates believed it was, then there is a creative element associated with it, at least in what the creation of new meaning is concerned (Glăveanu 2017a). Moreover, going back to the old roots of thinking about wonder in antiquity implies grasping the immense openness associated with questioning the obvious and making the familiar unfamiliar. This last process in particular implies the ability to see the world from new perspectives, a process that effectively transforms one’s reality and opens up the possible in human existence. Understanding how and why this is the case requires further theoretical elaboration.

A Theoretical Model

Despite centuries of interest in wondering, there are relatively few theoretical models of what this

phenomenon actually entails (for a philosophical exploration, see Parsons 1969) and even less empirical research (Carlsen and Sandelands 2014). This might well be because wonder is often considered in singular terms like “not knowing” or “dwelling into the unknown.” Yet what exactly triggers wondering, what are its processes, and how, if ever, could we cultivate it?

Before addressing these big questions, it is important to reflect for a moment on those phenomena that are similar to wonder and yet distinct from it, in particular curiosity and awe. The biggest commonality among them lies in the fact that they both connect us, one way or another, to an expanded field of possibility and drive us toward new knowledge about others, ourselves, and the world. At a practical level, all these processes involve raising questions and experiencing surprise. In other words, they either activate us and support our exploration or make us more sensitive and receptive to what lays in front of us. This active-passive dichotomy is important for understanding wonder, curiosity, and awe and what might differentiate between them.

Curiosity is an intrinsically activating state. To be curious means to be on the lookout for answers, to try things out and see what happens, to observe carefully (Engel 2015). Unsurprisingly then, curiosity ends (or is satisfied, as we typically say) when we get the knowledge we are looking for, i.e., when we understand. In other words, curiosity is triggered by a certain disturbance or unexpected event and ends in making us passive (again) or feeling satisfied. As such, it starts from the unfamiliar and it makes it familiar for us to be able to live with it undisturbed.

Awe does almost the opposite. Instead of activating, the unfamiliar unsettles us at such a deep level that it makes the person passive, unable to move (that is why the state of awe is often described as taking one’s breath away). We are in awe when we witness magnificent, overpowering, transcendental scenes or events. Scenes and events that might even terrify us. In fact, the sublime was how eighteenth-century philosophers (Burke 1958) referred to being in awe, a special state of mind that combines a sense of the beautiful and the terrible. The rising sun over the

planet Earth, seen from space, or a volcano eruption, admired from afar, can make us experience the sublime. We can note here a condition for this experience: We must feel safe from the terror of the scene before us and free to appreciate its aesthetic, transcendental dimensions.

Where does this leave wonder? On the continuum between passive awe and active curiosity, wonder sits in the middle, balancing surprise and receptivity with engagement and exploration (for a similar view, see Kareem 2014). Which is not to say that wonder is simply of combination of awe and curiosity, but that it shares characteristics with both. The intensity of feeling might be lower in wonder than awe, but wondering does make us marvel at the world. Conversely, we raise questions when we wonder, yet these do not aim to make the unfamiliar familiar, like in curiosity, but make the familiar unfamiliar. In wonder we question what we think we know and not only what we already know we do not know. In the end, the defining feature of wonder is that it helps us see the world anew by problematizing existing knowledge and opening us up to a field of possibility. As soon as we decide for one option within this field, we stop wondering. Thus, what wonder does is maintain us in a state of openness and uncertainty that is both tense and enchanting. It helps us explore what we do not understand without the promise of knowledge. In this, it is a state of mind unlike any other.

How exactly we can analytically describe the experience of wondering is, therefore, an important question. There are a few phenomenological studies of wonder (e.g., Parsons 1969) that usefully describe the thoughts and emotions involved in this phenomenon. However, we are yet to develop an account that is both analytical in its approach, distinguishing between different facets and processes, and holistic in its understanding of wondering as a unitary experience. I recently attempted to elaborate such a theoretical model (see Glăveanu 2020) which is summarized briefly as follows.

As noted above, wonder is unique in its integration of two dimensions: the receptivity of being surprised by a thought, object, or event, and the active exploration of it. This distinction is well noted in the literature, where scholars refer to

these “stages” in terms of wondering at and wondering about, respectively. Importantly, these two facets are interrelated at a deeper level than simply following or supporting each other. Just wondering at or wondering about results in a partial experience, one that we might not even call wonder anymore (but, as we have seen, place it closer to either awe or curiosity). So, what is it that “holds” the experience of wonder together?

To answer this last question we need to return to the idea that wondering relates as much to knowledge as it does to the possible. While centuries of thinking about wonder grounded it firmly in the discourse of knowing, not knowing, and getting to know, they also constructed this phenomenon in oppositional terms: active or passive, cognitive or emotional, useful or troublesome, and so on. In order to transcend these dichotomies, it useful to remember that the possible is both a trigger and outcome of wondering. It is by getting the sense of an expanded sense of possibility, for thinking and/or action, that we are prompted to wonder and, equally, the act of wondering explores and oftentimes expands this field of possibility.

In many ways, thus, wondering at can be conceptualized as becoming aware of the possible and, at the same time, exploring the possible. What unites these two is excitement about the possible or the emotional reaction that accompanies the realization that there is more to reality than we perceive or that we previously thought there would be (for details, see Glăveanu 2020). The dynamic relation between these three “elements” is captured in Fig. 1 below:

What is crucial to remember here is that the processes from Fig. 1 are not separate and do not operate independently of each other. The experience of wonder is a unitary experience, even if, at

different moments in time, it can be dominated by one of another of its facets. For example, encountering an unexpected object or getting to see a familiar object in a completely new light is likely to make us aware of an expanded field of possibility. But this awareness would be lost if we, almost at the same time, would not feel excited or motivated to pursue this insight and consider what else is there and what might come out of it.

Awareness, excitement, and exploration are intimately related within wondering and it is precisely this relationship that matters when considering the practical implications of how, when, and why we wonder.

Practical Implications

Why do we need the experience of wonder in our lives? After all, maybe the enemies of Socrates had a point when they said that wondering at best wastes our time and, at worst, makes us detached from reality and cynical toward any kind of established knowledge. As such, before addressing the practical implications of this phenomenon, a few observations are needed.

First of all, wondering – together with curiosity and creative expression – has a crucial part to play in our development and well-being (Nussbaum 2001; Chouinard 2007; Fuller 2009). In wonder, we take some distance from how things appear to be and think deeply about them. In order to be able to do this, we need to feel safe and to trust that we can take risks and really think freely. All of these are key preconditions for a healthy development. Second, wonder does not make us more cynical but, if anything, more open to the experience of other people. Socrates was not mocking his disciples for trying to know things but accompanying them through this process with a sense of openness and authentic interest in the other. These qualities do not make us less engaged in society but more willing to listen, to learn, and to act.

The conceptual model I outlined in this entry, including the awareness of, excitement for, and exploration of the possible, has some concrete benefits. Without it, we would not be able, for instance, to identify and to cultivate an experience

Wonder, Fig. 1 A conceptual model of wonder

of wonder that is “complete” rather than partial. An experience that leads us to the benefits mentioned above instead of reducing them to distractions and unenthusiastic forms of exploration.

Taking the example of education, teachers might be tempted in the classroom to use all sorts of surprising facts (including stories and videos) that make students think and question what they thought they knew. This falls under developing a sense of the possible or the process referred to as “wondering at,” the one that helps students connect on a personal level with the topic at hand. But does it help them make new meaning out of it and use this meaning to remain open to their unfolding experience? Not unless they are given the tools to properly explore the reason for their surprise, in other words, the tools to explore the possible and to “wonder about” it. These tools can be material, for instance a useful embodied exercise, or symbolic, in the form of a handout or a set of instructions. Meanwhile, bringing together wondering at and about, students need to remain motivated to explore, able to discover new surprises, and be excited about the possibilities associated with them. In this way, awareness, excitement, and exploration “collaborate” in creating an experience of wonder that is wide ranging, generative, and able to lead to deeper-level transformation (for a call for teaching that fuels curiosity, wonder, and imagination, see Engel 2011).

Wonder matters in education because students tend to experience too little of it at school. This is especially concerning given that classrooms should be precisely places where wonder – the experience of not knowing and wanting to understand – should thrive. Unfortunately, teachers often leave little space for wondering in actual classrooms because they almost immediately want to replace the experience of not knowing in their students with that of knowing. More than this, their aim is to have students know the “right,” oftentimes single answer. Despite an almost natural association between the aims of education and the outcomes of wonder, teachers are more often than not inclined to eliminate uncertainty and doubt from the classroom rather than foster it (with some exceptions, of course, see Beghetto 2018). It is therefore all the more important to become aware

of the fact that hindering wonder in educational processes means disconnecting students from a fruitful relation to what is possible and effectively impeding their exploration of new possibilities.

The same largely applies to work in organizations. Here, unlike schools, wondering and its companions – uncertainty and doubt – are often deliberately suppressed. A leader who wonders “too much” might well lose track of what is happening in the organization. A worker who does the same risks becoming aware of too many new possibilities and walking away or not doing the job properly. Organizations, by and large, aim for stability and productivity rather than support creativity and wonder (Lahlou and Beaudouin 2016). This is, at least, what we usually believe, but doesn’t this state of affairs apply more to twentieth-century firms and industries? Today we are repeatedly told that organizations need to be smart, agile, and ready to embrace change if they are to survive and grow. The characteristics above require a wondering mind. They ask for leaders and employees who are able to step back from the here and now of the situation they are in and question it, to imagine alternatives and build different futures. There is, therefore, a strong argument to be made that the processes of wonder we should try to cultivate in the classroom are highly relevant for the workplace as well.

And also beyond work, wonder is fundamental for living in society together with others and as an engine of social change. The past decades have seen an increase in protests and revolutions worldwide, few of them successful, many of them ineffective in the short and medium term at least. And yet, people find highly original ways to collectively express their call for a different society. New forms of activism and artivism emerge every day, animated by a shared desire to imagine the world different than how it is (see also Harrebye 2016). This constant questioning of convention and of the taken for granted is paired with a renewed sense of freedom and possibility: the fundamental characteristics of wondering. Previously, I wrote about the notion of “collective wonder” in social movements (Glăveanu 2017b), by which I do not imply that the collective itself wonders – individuals wonder, but their

experience is deeply social, shared with others, and in touch with the hopes and dreams of people close and far, even people they never got to meet personally. The value of wonder in society, as Socrates knew very well, is to unsettle the status quo and unleash the power of the imagination. In a world plagued by a variety of crises – from environmental to economic, social, and political – it is our capacity to wonder, separately and together, that helps us delve into the possible and experience the world as it yet might be.

Conclusion

I have argued in this entry that wonder is a fundamental type of human experience. What makes it eminently human (although we should be open to the possibility that some animals are able to entertain basic forms of wondering) is the fact that it opens up the possible in our existence. There are many phenomena, many of them covered in these pages, that relate to possibility and enable it. The particular role of wonder is to give us one of the most direct experiences of the possible. It is a peculiar experience in that it does not aim toward a certain outcome but embodies the openness, freedom, uncertainty, excitement, and uneasiness with which we usually approach the possible in our lives. Wondering has a variety of outcomes. It accompanies learning, it enriches our personal and working life, and it helps communities come together in an effort of reimagining the social world. But these outcomes come about when we feel safe enough to explore possibilities, to make mistakes, and when we accept that not knowing is a productive state of mind. Embracing these premises, however, requires us to overcome society's obsession with certainty, efficiency, and self-assured knowledge. That was no easy task in Socrates' time, and it certainly is not made any easier today.

Z

Zone of Proximal Development

Ingunn Johanne Ness

Faculty of Psychology, Centre for the Science of Learning and Technology (SLATE), University of Bergen, Bergen, Norway

Abstract

The zone of proximal development (ZPD) is a concept mostly associated with Lev Vygotsky, a Russian psychologist. The concept is primarily concerned with social and participatory learning and refers to the space between what a child can do on his or her own and what the child can do with help from someone more capable. However, the ZPD is about more than passive scaffolding from the more capable other. Instead it is closely connected to the idea of expanding the possible, using one's imagination, and pushing boundaries for what is known. This entry starts with defining the ZPD, and then the central part of the entry outlines the zone's core principles and elaborates how the ZPD involves creativity, play, and emotions. Positive emotions make it easier to play with ideas and what is possible thinking. Play is a source for development, and Vygotsky's ideas on creativity, play, and imagination can inspire how teachers teach. When children listen to the teacher or to each other's

experiences, they will be able to think in new ways, and the possible is broadened.

Keywords

Creativity · Zone of proximal development · Vygotsky · Play · Emotions · Dialogism · Experience · Imagination · Sociocultural psychology

The zone of proximal development is a well-known concept associated with the Russian psychologist Lev Vygotsky. It has been regularly interpreted and reinterpreted over the years, and while the bulk of the research and theorizing has taken place in educational contexts and learning situations, the zone of proximal development (ZPD) holds a special interest for both developmental and cognitive psychologists. Hence Vygotsky's ideas have been included in studies in a variety of fields – from intelligence testing (Brown and Ferrara 1985; Campione et al. 1984) to memory (Rogoff and Gardner 1984) and problem-solving (Wertsch 1979).

Even though it seems to be publicly accepted that it was Vygotsky that originally articulated the concept of ZPD, he states that it came from American and German authors. While many of Vygotsky's sources which formed his inspiration have been discovered and while he was clearly indebted to the work of his contemporaries, as noted by van der Veer and Valsiner (1991,

pp. 347–348), it has so far not been possible to find proof that his theory actually was formulated by others (van der Veer and Valsiner 1991, p. 347). His thinking was original, and it seems likely that it is a good example of Vygotsky's own creative synthesizing (Hasse 2001).

This entry will start with defining the ZPD and explore how the concept is connected to creativity, play, and emotions. Vygotsky's ideas on creativity, play, and imagination can inspire how teachers teach. The ZPD emphasizes the child's independent performance, but at the same time it focuses on how cognitive processes are stimulated and developing through imagination and play in a supportive environment. When these conditions are present, there will be a widening of the possible by pushing the boundaries for what is known to the child.

Defining the ZPD

As a concept, the ZPD is primarily concerned with social and participatory learning. Perhaps the most common definition is that it refers to the space between what a child can do on his or her own and what the child can do with help from someone more capable: "the distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem solving under adult guidance, or in collaboration with more capable peers" (Vygotsky 1978, p. 86). The central tenet of the theory is that when someone faces a task or a problem, the person can perform better with mediated assistance. This assistance can come from any person who has a better understanding, more experience, or a higher ability level than the learner, with respect to a particular task or process: "the more knowledgeable other." Even though this more knowledgeable other is often the teacher or an adult, it can be any person, older or younger, as long as he or she has more knowledge.

The zone of proximal development has many characteristics and is thus defined in many ways. According to Lobman (2010, pp. 202–203), several characterizations of the ZPD actually also

exist in Vygotsky's own writing (Holzman 2009; Newman and Holzman 1993). Still, the ZPD has mostly been defined as an instructional tool through which a more developed adult or peer provides just enough support for a less developed child to do something they could not do independently (Bodrova and Leong 1996; Rogoff and Gardner 1984; Wood et al. 1976).

However, Lobman points to Newman and Holzman (1993), who move beyond an instrumental definition of ZPD and perceive the ZPD as a creative, improvisational activity of people creating environments where there is room for both children and adults to take risks and make mistakes, at the same time as they support each other to perform tasks that they are not yet able to master on their own. Consequently, the ZPD is an ever-changing distance between being and becoming, rather than being a tool for learning pieces of information. In this way, the ZPD is not a concrete technique but instead an activity in which people can collectively engage and develop. Lobman (2010) states that such a view of the ZPD then shifts from putting focus on learning *in* the ZPD toward the active creation *of* the ZPD. According to this perspective, the zone of proximal development, as seen by Vygotsky, is indeed socially and actively created and can be seen as a process and not an entity – which again provides a way to understand human development that puts creativity at center stage with a focus on the possible and how learning is stimulated and cognitive processes develop.

Scaffolding

Closely connected to ZPD is the concept of "scaffolding" which was first developed by Wood et al. (1976). The metaphor is closely connected to the building industry and based on Vygotsky's concepts of learning and development. Children will need support, a scaffold, in different learning situations, and scaffolding encompasses both modelling and imitation to help the child to solve a task beyond what the child can do on its own (Wood et al. 1976, p. 90). The more the child learns, the tasks in which he or she can be engaged

in become more difficult – and in this way the zone is always changing. Scaffolding supports the child to develop and learn more.

In later years, however, there have been ongoing discussions about the ZPD and especially how knowledge is developed between people through interpersonal scaffolding (John-Steiner and Mahn 1996; Wells 1999). As outlined above, the majority of the research literature describes scaffolding as a process that enables a child or a novice to solve a problem, carry out a task, or achieve a goal that would be beyond the person's unassisted efforts (Wood et al. 1976). In this way, the term scaffolding could be taken to infer a process going one way where the “scaffolder” constructs the scaffold alone and presents it for the use to the novice (Daniels 2008). On the other hand, Newman et al. (1989) suggest a more relational approach: that the ZPD is created through a negotiation between the learner and the more advance partner, rather than through the donation of a scaffold as some kind of prefabricated climbing frame. In this way, both the learner and the more capable other will develop.

Griffin and Cole (1984) therefore criticize the scaffolding metaphor and claim that different settings and activities give rise to spaces within the ZPD which involve creative exploration rather than pedagogic domination (Daniels 2008). Valuing that space is at the heart of Griffin and Cole (1984) position; they argue for a dialogical interpretation of what Wertsch would term “mediated action” within a zone of proximal development in which the learner always brings a creative response to instruction or information given (Daniels 2008, p. 68). On deeper consideration, we find that there are various forms of mediation that affect progress within a ZPD (e.g., Daniels 2007; Smagorinsky 2008; Thompson 2012a, b). For instance, we can see it in peer collaboration involving critical thinking, problem-solving, or making decisions and scaffolding of a task.

Creativity and ZPD

There are parallels between Vygotsky's view on creativity and his theory on ZPD. The theory on

ZPD emphasizes the child's independent performance but also draws attention to the way in which the cognitive processes are immature and in the process of developing. According to Vygotsky, creative processes also involve the ability to think in concepts (Smolucha and Smolucha 1986) – which is an ability that first and foremost develops during adolescence and then matures in adulthood. In both artistic and scientific contexts, creativity will require an interplay between imagination and conceptual thinking. This will continue to develop throughout the life span (John-Steiner et al. 2010).

According to Vygotsky, imagination is the basis for all creative activity and is involved in every aspect connected to creation: “imagination, as the basis of all creative activity, is an important component of absolutely all aspects of cultural life, enabling artistic, scientific, and technical creation alike” (Vygotsky 1930/2004, p. 9). Vygotsky (1930/2004) claimed that creativity exists wherever the human imagination combines, changes, and creates something new. Vygotsky (1930/2004) described fantasy and creativity as any human action that results in something new – even if this is only known to that individual person. This is an everyday view on creativity as something that does not have to result in a big innovation. While for Vygotsky creativity was something every day that didn't have to result in big historical work, at the same time he acknowledged that such breakthroughs were possible. Vygotsky believed that those higher forms of creativity are not within everyone's reach for everybody but still that these big innovations are built on similar creative processes as in the minor discoveries:

Of course, the highest expressions of creativity remain accessible only to a select few human geniuses; however, in the everyday life that surrounds us, creativity is an essential condition for existence and all that goes beyond the rut of routine and involves innovation, albeit only a tiny amount, owes its existence to the human creative process. (Vygotsky 1930/2004, pp. 10–11)

These concepts – imagination, creativity, and fantasy – are used interchangeably throughout Vygotsky's work, along with the term “creative

imagination.” He was strongly influenced by Ribot (1906/2010) who presented the first holistic psychological theories on creative imagination: recombination theory. Ribot’s focus was, in particular, on how imagination can be seen as a continuum from reproduction to production as in creating something new. Vygotsky thought it was important to divide between what already exists and what is new. According to Vygotsky, either people will reproduce activities (that do not lead to something new and will thus be linked to memory) or people can engage in more innovative and creative activities like perhaps combining elements from previous experience so that these result in new combinations (which then will be linked to imagination and not memory). The latter is what Vygotsky defined as creative imagination. Our fantasy and our imagination are dependent on previous experiences in order to create new combinations (Vygotsky 1930/2004):

... imagination takes on a very important function in human behaviour and human development. It becomes the means by which a person’s experience is broadened, because he can imagine what he has not seen, can conceptualize something from another person’s narration and description of what he himself has never directly experienced... (Vygotsky 1930/2004, p. 17).

In other words, how creative a person can be will depend on how many different experiences the person has – but it is not necessary to experience everything directly oneself; it is enough to listen to other people’s descriptions.

Play and ZPD

Vygotsky claimed that creative processes are involved already in early childhood and points to how play is a way for the child to be creative by – among other things – taking on different roles. The child will use the experiences she or he has gotten so far in life as a point of departure for further elaboration. In this there is a social aspect, and it is through imagination children learn how to act in human relations, activities, and situations. When going through these processes with playful exploration, the children develop and grow

(Marjanovic-Shane 2010). Vygotsky saw imagination as an internalized play that developed in interaction with others (Moran and John-Steiner 2003).

According to Holzman (2010), Vygotsky claimed that play has an essential role in early childhood development and stated that: “In play a child always behaves beyond his average age, above his daily behaviour; in play it is as though he were a head taller than himself” (Vygotsky 1978, p. 102). Here we see a clear connection to development which has gone on to influence researchers in education all over the world. Play is a source for development, and Vygotsky’s ideas on creativity, play, and imagination can inspire how teachers teach. When children listen to the teacher or to each other’s experiences, they will be able to use their imagination and think in new ways. Put in another way: the possible is broadened. This process in which they combine previous knowledge with new experiences results in a change in the children’s individual knowledge. In this way, change is a link between creativity and learning (Glaveanu et al. 2019). A way to share experiences in, for instance, the classroom is to let the pupils bring an item from home that means something special for them. This can be a toy, a dress, or even a play, and then let them tell and share to each other what makes this special item so special. This can help the pupils to feel “seen” and safe, and it is also a fun way to learn. Positive emotions stimulate imagination and enhance learning.

Emotions and ZPD

Vygotsky’s ideas on emotions are perhaps not very well known, but they are fundamental to an understanding of his theory on the human mind and the zone of proximal development. His concept of ZPD can be understood in more depth by looking at how Vygotsky’s thought on emotions influences learning:

Thought is not born of other thoughts. Thought has its origins in the motivating sphere of consciousness, a sphere that includes our inclinations and needs, our interests and impulses, and our affect

and emotions. The affective and volitional tendency stands behind thought. Only here do we find the answer to the final “why” in the analysis of thinking. (Vygotsky 1934/1987, p. 282)

Here Vygotsky explores the relationship between thoughts, emotions, language, and consciousness. By including emotional variables when studying ZPD, we will also see how children’s experiences and emotions influence both this zone and their learning and development.

For instance, if pupils in school feel that the gap between what they can do on their own and what the teacher expects them to master is too wide, they can become worried – and that will hinder their learning. If they become afraid of failing, this can hinder their creativity and openness for learning (Mahn and John-Steiner 2002).

Emotions and supportive relations are according to Vygotsky crucial for children’s learning and will help children to use their imagination. Research on creativity and emotions in a socio-cultural perspective show that when people feel safe in a situation, we relax and go into a “broaden-and-build mode” (Fredrickson and Branigan 2005). This will make it easier to play with ideas and to engage in creative scenario thinking. According to Marjanovic-Shane, Connery, and John-Steiner (2010, p. 224), emotions are intertwined in learning and teaching and exist as important dimensions in the quality of all learning and teaching situations. Marjanovic-Shane et al. (2010, p. 225) claims that the way learning environments are organized will either foster or hinder the emotional and relational conditions for creative activities. Learning is a creative act. Positive relations will encourage children to “let go” and to get engaged in learning and in other creative processes. Emotional support that follows positive relations and respect is an important condition for creativity and learning. Emotional support can create emotional safety which is crucial to learning. Mahn and John-Steiner (2002, pp. 5–6) claim that “the Gift of Confidence” is reciprocal emotional support that can help anyone that is in the beginning of their learning of something (language, maths, or something else). Self-confidence comes from support and is an important part of the ZPD and the creative

processes that we associate with Vygotsky. Positive emotions make it easier to play with ideas and what is possible thinking.

Summary & Conclusion

The zone of proximal development has many aspects and is about more than passive scaffolding from the more capable other. Vygotsky’s ideas on the ZPD and how this involves creativity, play, and imagination can inspire how teachers teach. This entry started by defining the ZPD, and then it has explored in more detail how the concept is connected to creativity, play, and emotions. The ZPD emphasizes the child’s independent performance, but at the same time, it focuses on how cognitive processes are stimulated and developing through imagination and play in a supportive environment. If the child becomes afraid of failing, this can hinder creativity and openness for learning. On the other hand, when these conditions are present and the child is supported and encouraged in play, this will stimulate imagination and creativity. In this way, there will be a widening of the possible and what the child can learn by pushing the boundaries for what is known to the child.
